The Duke of Leeds has an original scene in the "Beggar's Opera," painted by Hogarth. It is that in which Lucy and Polly are on their knees, before their respective fathers, to intercede for the life of the hero of the piece. All the figures are either known or supposed to be portraits. If we are not misinformed, the late Sir Thomas Robinson (perhaps better known by the name of Long Sir Thomas) is standing in one of the side-boxes. Macheath, unlike his spruce representative on our present stage, is a slouching bully; and Polly appears happily disencumbered of such a hoop as the daughter of Peachum within our younger memories has worn. Mr Walpole has a picture of a scene in the same piece, where Macheath is going to execution. In this also the likenesses of Walker and Miss Fenton, afterwards duchess of Bolton (the first and original Macheath and Polly) are preserved. In the year 1726, when the affair of Mary Tofts, the rabbit-breeder of Godalming, engaged the public attention, a few of our principal surgeons subscribed their guinea a-piece to Hogarth, for an engraving from a ludicrous sketch he had made on that very popular subject. This plate, amongst other portraits, contains that of the St André, then anatomist to the royal household, and in high credit as a surgeon. In 1727, Hogarth agreed with Morris, an upholsterer, to furnish him with a design on canvas, representing the element of earth, as a pattern for tapestry. The work not being performed to the satisfaction of Morris, he refused to pay for it; and our artist, by a suit at law, recovered the money.

In 1730, Mr Hogarth married the only daughter of Sir James Thornhill, by whom he had no child. This union, indeed, was a stolen one, and consequently without the approbation of Sir James, who, considering the youth of his daughter, then barely 18, and the slender finances of her husband, as yet an obscure artist, was not easily reconciled to the match. Soon after this period, however, he began his "Harlot's Progress" (the coffin in the last place is inscribed Sept. 2. 1731); and was advised by lady Thornhill to have some of the scenes in it placed in the way of his father-in-law. Accordingly, one morning early, Mrs Hogarth undertook to convey several of them into his dining-room. When he arose, he inquired from whence they came; and being told by whom they were introduced, he cried out, "Very well; the man who can furnish representations like these can also maintain a wife without a portion." He designed this remark as an excuse for keeping his purse-strings close; but, soon after, became both reconciled and generous to the young people. An allegorical ceiling by Sir James Thornhill is at the house of the late Mr Huggins, at Headly Park, Hants. The subject of it is the story of Zephyrus and Flora; and the figure of a satyr and some others were painted by Hogarth.

In 1732, Hogarth ventured to attack Mr Pope, in a plate called "The Man of Taste;" containing a

view

Hogarth. view of the Gate of Burlington-house, with Pope whitewashing it and bespattering the duke of Chandos's coach. This plate was intended as a satire on the translator of Homer, Mr Kent the architect, and the earl of Burlington. It was fortunate for Hogarth that he escaped the lash of the former. Either Hogarth's obscurity at that time was his protection, or the bard was too prudent to exasperate a painter who had already given such proof of his abilities for satire.

Soon after his marriage, Hogarth had summer lodgings at South-Lambeth; and being intimate with Mr Tyers, contributed to the improvement of the Spring Gardens at Vauxhall, by the hint of embellishing them with paintings, some of which were the suggestions of his own truly comic pencil. For his assistance, Mr Tyers gratefully presented him with a gold ticket of admission for himself and his friends.

In 1733, his genius became conspicuously known. The third scene of his "Harlot's Progress" introduced him to the notice of the great. At a board of treasury which was held a day or two after the appearance of that print, a copy of it was shown by one of the lords, as containing, among other excellencies, a striking likeness of Sir John Gonson. It gave universal satisfaction: from the treasury each lord repaired to the print-shop for a copy of it, and Hogarth rose completely into fame.

The ingenious Abbé Du Bos has often complained that no history-painter of his time went through a series of actions, and thus, like an historian, painted the successive fortune of an hero from the cradle to the grave. What Du Bos wished to see done, Hogarth performed. He lances out his young adventurer a simple girl upon the town, and conducts her through all the vicissitudes of wretchedness to a premature death. This was painting to the understanding and to the heart; none had ever before made the pencil subservient to the purposes of morality and instruction: a book like this is fitted to every soil and every observer; and he that runs may read. Nor was the success of Hogarth confined to his persons. One of his excellencies consisted in what may be termed the furniture of his pieces; for as, in sublime and historical representations, the fewer trivial circumstances are permitted to divide the spectator's attention from the principal figures, the greater is their force; so, in scenes copied from familiar life, a proper variety of little domestic images contributes to throw a degree of verisimilitude on the whole. "The Rake's levee-room," says Mr Walpole, "the nobleman's dining-room, the apartments of the husband and wife in *Marriage à la Mode*, the alderman's parlour, the bed-chamber, and many others, are the history of the manners of the age."

In 1745, Hogarth sold about 20 of his capital pictures by auction; and in the same year acquired additional reputation by the six prints of "*Marriage à la Mode*," which may be regarded as the ground-work of a novel called "*The Marriage Act*," by Dr Shebbeare, and of "*The Clandestine Marriage*."

Soon after the peace of Aix la Chapelle, he went over to France, and was taken into custody at Calais while he was drawing the gate of that town; a circumstance which he has recorded in his picture, intitled, "*O the Roast Beef of Old England!*" pub-

lished March 26. 1749. He was actually carried before the governor as a spy, and after a very strict examination committed a prisoner to Granfire, his landlord, on his promising that Hogarth should not go out of his house till he was to embark for England.

In 1753, he appeared to the world in the character of an author, and published a quarto volume, intitled, "*The Analysis of Beauty*, written with a view of fixing the fluctuating ideas of taste." In this performance he shows, by a variety of examples, that a curve is the line of beauty, and that round swelling figures are most pleasing to the eye; and the truth of his opinion has been countenanced by subsequent writers on the subject. In this work, the leading idea of which was hieroglyphically thrown out in a frontispiece to his works in 1745, he acknowledges himself indebted to his friends for assistance, and particularly to one gentleman for his corrections and amendments of at least a third part of the *wording*. This friend was Dr Benjamin Hoadley the physician, who carried on the work to about the third part, Chap. IX. and then, through indisposition, declined the friendly office with regret. Mr Hogarth applied to his neighbour Mr Ralph; but it was impossible for two such persons to agree, both alike vain and positive. He proceeded no farther than about a sheet, and they then parted friends, and seem to have continued such. The kind office of finishing the work, and superintending the publication, was lastly taken up by Dr Morell, who went through the remainder of the book. The preface was in like manner corrected by the Rev. Mr Townley. The family of Hogarth rejoiced when the last sheet of the "*Analysis*" was printed off; as the frequent disputes he had with his coadjutors, in the progress of the work, did not much harmonize his disposition. This work was translated into German by Mr Mylins, when in England, under the author's inspection; and the translation was printed in London, price five dollars. A new and correct edition was in 1754 proposed for publication at Berlin, by Ch. Fr. Vok, with an explanation of Mr Hogarth's satirical prints, translated from the French; and an Italian translation was published at Leghorn in 1761.

Hogarth had one failing in common with most people who attain wealth and eminence without the aid of liberal education.—He affected to despise every kind of knowledge which he did not possess. Having established his fame with little or no obligation to literature, he either conceived it to be needless, or decried it because it lay out of his reach. His sentiments, in short, resembled those of Jack Cade, who pronounced sentence on the clerk of Chatham because he could write and read. Till, in evil hour, this celebrated artist commenced author, and was obliged to employ the friends already mentioned to correct his "*Analysis of Beauty*," he did not seem to have discovered that even spelling was a necessary qualification; and yet he had ventured to ridicule the late Mr Rich's deficiency as to this particular, in a note which lies before the *Rake* whose play is refused while he remains in confinement for debt. Previous to the time of which we are now speaking, one of our artist's common topics of declamation was the uselessness of books to a man of his profession. In "*Beer-street*," among other volumes consigned by him to the pastry-cook, we find Turn-

bull

Hogarth. bull "on Ancient Painting;" a treatise which Hogarth should have been able to understand before he ventured to condemn. Garrick himself, however, was not more ductile to flattery. A word in praise of "Sigismunda," his favourite work, might have commanded a proof print, or forced an original sketch out of our artist's hands. The following authenticated story of our artist will also serve to show how much more easy it is to detect ill placed or hyperbolical adulation respecting others than when applied to ourselves. Hogarth being at dinner with the great Cheseelden and some other company, was told that Mr John Freke, surgeon of St Bartholomew's-hospital, a few evenings before, at Dick's Coffee-house, had asserted that Greene was as eminent in composition as Handel. "That fellow Freke," replied Hogarth, "is always shooting his bolt absurdly one way or another! Handle is a giant in music; Greene only a light Florimel kind of a composer."—"Aye," says our artist's informant; "but at the same time Mr Freke declared you were as good a portrait-painter as Vandyck."—"There he was in the right," adds Hogarth; "and so by G—I am, give me my time, and let me choose my subject!"

A specimen of Hogarth's propensity to merriment, on the most trivial occasions, is observable in one of his cards requesting the company of Dr Arnold King to dine with him at the Mitre. Within a circle, to which a knife and fork are the supporters, the written part is contained. In the centre is drawn a pye, with a mitre on the top of it; and the invitation of our artist concludes with the following sport on the Greek letters—to *Eta Beta Pi*. The rest of the inscription is not very accurately spelt. A quibble by Hogarth is surely as respectable as a conundrum by Swift.

In one of the early exhibitions at Spring-Gardens, a very pleasing small picture by Hogarth made its first appearance. It was painted for the Earl of Charlemont, in whose collection it remains, and was intitled "Picquet, or Virtue in Danger;" and shows us a young lady who during a *tête-à-tête* had just lost all her money to a handsome officer of her own age. He is represented in the act of returning her a handful of bank bills, with the hope of exchanging them for a softer acquisition and more delicate plunder. On the chimney-piece a watch-case and a figure of Time over it, with this motto—NUNC. Hogarth has caught his heroine during this moment of hesitation, this struggle with herself, and has marked her feelings with uncommon success.

In the "Miser's Feast," Mr Hogarth thought proper to pillory Sir Isaac Shard, a gentleman proverbially avaricious. Hearing this, the son of Sir Isaac, the late Isaac Pacatus Shard, Esq; a young man of spirit, just returned from his travels, called at the painter's to see the picture; and, among the rest, asking the Cicerone "whether that odd figure was intended for any particular person;" on his replying "that it was thought to be very like one Sir Isaac Shard," he immediately drew his sword and flashed the canvas. Hogarth appeared instantly in great wrath; to whom Mr Shard calmly justified what he had done, saying "that this was a very unwarrantable licence; that he was the injured party's son, and that he was ready to defend any suit at law;" which, however, was never instituted.

Nº 156.

About 1757, his brother-in-law, Mr Thornhill, resigned the place of king's-ferjeant-painter in favour of Mr Hogarth.

The last remarkable circumstance of his life was his contest with Mr Churchill. It is said that both met at Westminster-hall; Hogarth to take by his eye a ridiculous likeness of the poet, and Churchill to furnish a description of the painter. But Hogarth's print of the poet was not much esteemed, and the poet's letter to him was but little admired. Some pretend, indeed, to say that it broke the painter's heart; but this we can from good authority say is not true. Indeed the report falls of itself; for we may as well say, that Hogarth's pencil was as efficacious as the poet's pen, since neither long survived the contest.

It may be truly observed of Hogarth, that all his powers of delighting were restrained to his pencil. Having rarely been admitted into polite circles, none of his sharp corners had been rubbed off, so that he continued to the last a gross uncultivated man. The slightest contradiction transported him into rage. To some confidence in himself he was certainly intitled: for, as a comic painter, he could have claimed no honour that would not most readily have been allowed him; but he was at once unprincipled and variable in his political conduct and attachments. He is also said to have beheld the rising eminence and popularity of Sir Joshua Reynolds with a degree of envy; and, if we are not misinformed, frequently spoke with asperity both of him and his performances. Justice, however, obliges us to add, that our artist was liberal, hospitable, and the most punctual of paymasters; so that, in spite of the emoluments his works had procured to him, he left but an inconsiderable fortune to his widow. His plates indeed are such resources to her as may not speedily be exhausted. Some of his domestics had lived many years in his service; a circumstance that always reflects credit on a master. Of most of these he painted strong likenesses on a canvas still in Mrs Hogarth's possession.

Of Hogarth's lesser plates many were destroyed. When he wanted a piece of copper on a sudden, he would take any from which he had already worked off such a number of impressions as he supposed he should sell. He then sent it to be effaced, beat out, or otherwise altered to his present purpose. The plates which remained in his possession were secured to Mrs Hogarth by his will dated, Aug. 12. 1764, chargeable with an annuity of L. 80 to his sister Anne, who survived him. When, on the death of his other sister, she left off the business in which she was engaged, he kindly took her home, and generously supported her, making her at the same time, useful in the disposal of his prints. Want of tenderness and liberality to his relations was not among the failings of Hogarth.

The following character of Hogarth as an artist is given by Mr Gilpin in his *Essay on Prints*. "The works of this master abound in true humour; and satire, which is generally well directed: they are admirable moral lessons, and a fund of entertainment suited to every taste; a circumstance which shows them to be just copies of nature. We may consider them too as valuable repositories of the manners, customs, and dresses of the present age. What a fund of entertainment would a collection of this kind afford, drawn from every period of the history of Britain?—How far

Hogarth. far the works of Hogarth will bear a *critical examination*, may be the subject of a little more enquiry.

"In *design*, Hogarth was seldom at a loss. His invention was fertile, and his judgment accurate. An improper incident is rarely introduced, a proper one rarely omitted. No one could tell a story better, or make it in all its circumstances more intelligible. His genius, however, it must be owned, was suited only to *low* or *familiar* subjects; it never soared above *common* life: to subjects naturally sublime, or which from antiquity or other accidents borrowed dignity, he could not rise. In *composition* we see little in him to admire. In many of his prints the deficiency is so great as plainly to imply a want of all principle; which makes us ready to believe, that when we do meet with a beautiful group, it is the effect of chance. In one of his minor works, the *Idle Prentice*, we seldom see a crowd more beautifully managed than in the last print. If the sheriff's officers had not been placed in a line, and had been brought a little lower in the picture, so as to have formed a pyramid with the cart, the composition had been unexceptionable; and yet the first print of this work is such a striking instance of disagreeable composition, that it is amazing how an artist who had any idea of beautiful forms could suffer so unmasterly a performance to leave his hands. Of the *distribution of light* Hogarth had as little knowledge as of *composition*. In some of his pieces we see a good effect, as in the *Execution* just mentioned; in which, if the figures at the right and left corners had been *kept down* a little, the light would have been beautifully distributed on the fore-ground, and a fine secondary light spread over part of the crowd. But at the same time there is so obvious a deficiency in point of effect in most of his prints, that it is very evident he had no principles. Neither was Hogarth a master in *drawing*. Of the muscles and anatomy of the head and hands he had perfect knowledge; but his trunks are often badly moulded, and his limbs ill set on: yet his figures, upon the whole, are inspired with so much life and meaning, that the eye is kept in good-humour in spite of its inclination to find fault. The author of the *Analysis of Beauty*, it might be supposed, would have given us more instances of *grace* than we find in the works of Hogarth; which shows strongly that theory and practice are not always united. Many opportunities his subjects naturally afford of introducing graceful attitudes, and yet we have very few examples of them. With instances of picturesque grace his works abound. Of his *expression*, in which the force of his genius lay, we cannot speak in terms too high. In every mode of it he was truly excellent. The passions he thoroughly understood, and all the effects which they produce in every part of the human frame. He had the happy art also of conveying his ideas with the same precision with which he conceived them. He was excellent too in expressing any humorous oddity which we often see stamped upon the human face. All his heads are cast in the very mould of nature. Hence that endless variety which is displayed thro' his works; and hence it is that the difference arises between *his* heads and the affected caricatures of those masters who have sometimes amused themselves with patching together an assemblage of features from their own ideas. Such are *Spaniolet's*; which, though admirably executed, appear plainly to

VOL. VIII. Part II.

have no archetypes in nature. Hogarth's, on the other hand, are collections of natural curiosities. The *Oxford-heads*, the *Physician's-arms*, and some of his other pieces, are expressly of this humorous kind. They are truly comic, though ill-natured effusions of mirth: more entertaining than *Spaniolet's*, as they are pure nature; but less innocent, as they contain ill-directed ridicule.—But the species of expression in which this master perhaps most excels, is that happy art of catching those peculiarities of art and gesture which the ridiculous part of every profession contract, and which for that reason become characteristic of the whole. His counsellors, his undertakers, his lawyers, his usurers, are all conspicuous at sight. In a word, almost every profession may see in his works that particular species of affectation which they should most endeavour to avoid. The *execution* of this master is well suited to his subjects and manner of treating them. He etches with great spirit, and never gives one unnecessary stroke."

HOGSHEAD, in commerce, a measure of capacity containing 63 gallons.

HOGUE, a town and cape on the north-west point of Normandy in France; near which admiral Rook burnt the French admiral's ship called the *Rising Sun*, with 12 more large men of war, the day after the victory obtained by admiral Russell near Cherbourg in May 1692. W. Long. 2. 0. N. Lat. 49. 50.

HOIST, in sea-language, denotes the perpendicular height of a flag or ensign, as opposed to the fly, which signifies its breadth from the staff to the outer edge.

HOISTING signifies the operation of drawing up any body by the assistance of one or more tackles. Hoisting is never applied to the act of pulling up any body by the help of a single block, except in the exercise of extending the sails by drawing them upwards along the masts or stays, to which it is invariably applied.

HOKE-DAY, *Hock-Day*, or *Hock-Tuesday*, in our ancient customs (*dies Martis, quem quindenam pasche vocant*), the second Tuesday after Easter week; a solemn festival celebrated for many ages in England in memory of the great slaughter of the Danes in the time of king Ethelred, they having been in that reign almost all destroyed in one day in different parts of the kingdom, and that principally by women. This is still kept up in some counties; and the women bear the principal sway in it, stopping all passengers with ropes and chains, and exacting some small matter from them to make merry with. This day was very remarkable in former times, inasmuch as to be used on the same footing with Michaelmas for a general term or time of account. We find leases without date reserving so much rent payable *ad duos anni terminos, scil. ad le hoke-day, & ad festum sancti Michaelis*. In the accounts of Magdalen-college, Oxford, there is yearly an allowance *pro mulieribus hockantibus* of some manors of theirs in Hampshire; where the men hock the women on Mondays, and the women hock them on Tuesdays. The meaning of it is, that on that day the women in merriment stopped the way with ropes, and pulled passengers to them, desiring something to be laid out for pious uses.

HOKE-Day Money, or *Hoke Tuesday Money*, a tribute anciently paid the landlord, for giving his tenants and

Ho kien,
Holbein.

bondmen leave to celebrate hock-day, or hoke-day, in memory of the expulsion of the domineering Danes.

HO-KIEN-FOU, a city of China, and one of the principal in the province of Pe-tcheli. It has two cities of the second, and fifteen of the third, class in its district, but is remarkable for nothing but the neatness of its streets.

HOLBEIN (Hans), a celebrated painter, born at Basil in Switzerland in 1498, learned the rudiments of his art from his father, who was a painter; but soon showed his superior genius. In the town-house of Basil he painted our Saviour's Passion; and in the fish-market of the same city Death's Dance, and a Dance of Peasants, which were extremely admired; and Erasmus was so pleased with them, that he desired him to draw his picture, and was ever after his friend. He staid some years longer at Basil, till his necessities, occasioned by his own extravagance and an increasing family, made him comply with Erasmus's persuasions to go to England. In his journey he staid some days at Strasburg, where it is said he applied to a very great painter for work, who took him in, and ordered him to give a specimen of his skill. On which Holbein finished a piece with great care, and painted a fly on the most eminent part of it; after which he privately withdrew in the absence of his master, and pursued his journey, without saying any thing to any body. When the painter returned home, he was astonished at the beauty and elegance of the drawing; and especially at the fly, which he at first took for a real one, and endeavoured to remove it with his hand. He now sent all over the city for his journeyman; but after many inquiries, discovered that he had been thus deceived by the famous Holbein.—Holbein having in a manner begged his way to England, presented a letter of recommendation from Erasmus to Sir Thomas More, and also showed him Erasmus's picture. Sir Thomas, who was then lord-chancellor, received him with all the joy imaginable, and kept him in his house between two and three years; in which time he drew Sir Thomas's picture, and those of many of his relations and friends. Holbein one day happening to mention a nobleman who had some years before invited him to England, Sir Thomas was very solicitous to know who it was. Holbein said that he had forgot his title, but remembered his face so well, that he believed he could draw his likeness; which he did so perfectly, that the nobleman it is said was immediately known by it. The chancellor having now adorned his apartments with the productions of this great painter, resolved to introduce him to Henry VIII. For this purpose, he invited that prince to an entertainment; having, before he came, hung up all Holbein's pieces in the great hall, in the best order, and placed in the best light. The king, on his first entrance into this room, was so charmed with the sight, that he asked whether such an artist was now alive, and to be had for money? Upon this, Sir Thomas presented Holbein to his majesty; who immediately took him into his service, and brought him into great esteem with the nobility and gentry, by which means he drew a vast number of portraits. But while he was here, there happened an affair which might have proved fatal to him, had he not been protected by the king. On the report of this painter's character, a lord of the first quality came to see him

when he was drawing a figure after the life. Holbein sent to desire his lordship to defer the honour of his visit to another day; which the nobleman taking for an affront, broke open the door, and very rudely went up stairs. Holbein hearing a noise, came out of his chamber; and meeting the lord at his door, fell into a violent passion, and pushed him backwards from the top of the stairs to the bottom. However, immediately reflecting on what he had done, he escaped from the tumult he had raised, and made the best of his way to the king. The nobleman, much hurt, though not so much as he pretended, was there soon after him; and upon opening his grievance, the king ordered Holbein to ask his pardon. But this only irritated the nobleman the more, who would not be satisfied with less than his life; upon which the king sternly replied, "My lord, you have not now to do with Holbein, but with me: whatever punishment you may contrive by way of revenge against him, shall certainly be inflicted on yourself. Remember, pray, my lord, that I can whenever I please make seven lords of seven ploughmen, but I cannot make one Holbein of even seven lords." Holbein died of the plague at his lodgings at Whitehall in 1554. "It is amazing (says De Piles), that a man born in Switzerland, and who had never been in Italy, should have so good a *gusto*, and so fine a genius for painting." He painted alike in every manner; in fresco, in water-colours, in oil, and in miniature. His genius was sufficiently shown in the historical style, by two celebrated compositions which he painted in the hall of the Stillyard company. He was also eminent for a rich vein of invention, which he showed in a multitude of designs which he drew for engravers, statuaries, jewellers, &c. and he had this singularity, that he painted with his left hand.

HOLCUS, INDIAN MILLET OR CORN: A genus of the monœcia order, belonging to the polygamia class of plants; and in the natural method ranking under the 4th order, *Gramina*. The calyx of the hermaphrodite is an uniflorous or biflorous glume; the corolla is a glume with an awn; there are three stamina, two styles, and one seed. The male calyx is a bivalved glume; there is no corolla, but three stamina.

Species. Of this genus there are 13 species, two of which are natives of Britain. The most remarkable of these is the lanatus, or creeping soft-grass of Hudson; for the description and properties of which see AGRICULTURE, n° 59. The most remarkable of the foreign species is the sorghum, or Guinea-corn. The stalks are large, compact, and full eight feet high. In Senegal the fields are entirely covered with it. The negroes, who call it *guiarnot*, cover the ears when ripe with its own leaves to shelter it from the sparrows, which are very mischievous in that country. The grain made into bread, or otherwise used, is esteemed very wholesome. With this the slaves in the West Indies are generally fed, each being allowed from a pint to a quart every day. The juice of the stalks is so agreeably luscious, that, if prepared as the sugar-canes, they would afford an excellent sugar. The negroes on the coast of Guinea make of two kinds of millet a thick-grained pap called *couscous*, which is their common food.

HOLD, the whole interior cavity or belly of a ship, or all that part of her inside which is comprehended

Holbein
||
Hold.

Plate
CCXXXV.

Holder hended between the floor and the lower-deck throughout her whole length.—This capacious apartment usually contains the ballast, provisions, and stores of a ship of war, and the principal part of the cargo in a merchantman. The disposition of these articles with regard to each other, naturally falls under consideration in the article *STOWAGE*; it suffices in this place to say, that the places where the ballast, water, provisions, and liquors are stowed, are known by the general name of the *hold*. The several store-rooms are separated from each other by *bulk-heads*, and are denominated according to the articles which they contain, the *sail-room*, the *bread-room*, the *fish-room*, the *spirit-room*, &c.

HOLDER (William), a learned and philosophical Englishman, was born in Nottinghamshire, educated in Pembroke-hall Cambridge, and in 1642 became rector of Blechingdon of Oxford. In 1660 he proceeded D. D. was afterwards canon of Ely, fellow of the Royal Society, canon of St Paul's, sub-dean of the royal chapel, and sub-almoner to his majesty. He was a very accomplished person, and withal a great virtuoso: and he wonderfully distinguished himself, by making a young gentleman of distinction who was born deaf and dumb to speak. This gentleman's name was Alexander Popham, son of colonel Edward Popham, who was some time an admiral in the service of the long parliament. The cure was performed by him in his house at Blechingdon in 1659; but Popham losing what he had been taught by Holder after he was called home to his friends, was sent to Dr Wallis, who brought him to his speech again. Holder published a book, intitled "the Elements of Speech; an essay of inquiry into the natural Production of Letters: with an appendix concerning persons that are deaf and dumb, 1669," 8vo. In the appendix he relates how soon, and by what methods, he brought Popham to speak. In 1678, he published in 4to "a Supplement to the Philosophical Transactions of July 1670, with some reflections on Dr Wallis's letter there inserted." This was written to claim the glory of having taught Popham to speak, which Wallis in the said letter had claimed to himself; upon which the Doctor soon after published "a Defence of the Royal Society, and the Philosophical Transactions, particularly those of July 1670, in answer to the Cavils of Dr William Holder, 1678," 4to. Holder was skilled in the theory and practice of music, and wrote "a Treatise of the natural Grounds and Principles of Harmony, 1694," 8vo. He wrote also "a Discourse concerning Time, with Application of the natural Day, lunar Month, and solar Year, &c. 1694," 8vo. He died at Amen Corner in London, January 24. 1696-7, and was buried in St Paul's.

HOLDERNESS, a peninsula in the east-riding of Yorkshire, having the German sea on the east, and the Humber on the south. It had the title of an earldom, now extinct.

HOLDSWORTH (Edward), a very polite and elegant scholar, was born about 1688, and trained at Winchester school. He was thence elected demy of Magdalen college, Oxford, in July 1705; took the degree of M. A. in April 1711; became a college-tutor, and had many pupils. In 1715, when he was to be chosen

into a fellowship, he resigned his demyship and left the college, because unwilling to swear allegiance to the new government. The remainder of his life was spent in travelling with young noblemen and gentlemen as tutor: in 1741 and 1744 he was at Rome in this capacity. He died of a fever at Lord Digby's house at Colehill in Warwickshire, December 30. 1747. He was the author of the "*Muscipula*," a poem, esteemed a master-piece in its kind, and of which there is a good English translation by Dr John Hoadly, in vol. 5. of Dodsley's Miscellanies. He was the author also of a dissertation, intitled "*Pharsalia and Philippi*; or the two Philippi in Virgil's Georgics attempted to be explained and reconciled to History, 1741," 4to: and of "*Remarks and Dissertations on Virgil*; with some other classical Observations, published with several notes and additional remarks by Mr Spence, 1768," 4to. Mr Spence speaks of him in *Polymetis*, as one who understood Virgil in a more masterly manner than any person he ever knew.

HOLERACEÆ, (from *holus*, "pot-herbs"); the name of the 12th order in Linnæus's fragments of a natural method, consisting of plants which are used for the table, and enter into the economy of domestic affairs. See *BOTANY*, p. 459.

HOLIBUT, in ichthyology. See *PLEURONECTES*.

HOLIDAY (Dr Barten), a learned divine and poet, was the son of a taylor in Oxford, and born there about the year 1593. He studied at Christchurch college, and in 1615 took orders. He was before admired for his skill in poetry and oratory; and now distinguishing himself by his eloquence and popularity as a preacher, he had two benefices conferred on him in the diocese of Oxford. In 1618, he went as chaplain to Sir Francis Stewart, when he accompanied Count Gondamore to Spain. Afterwards he became chaplain to the king, and before the year 1626 was promoted to the archdeaconry of Oxford. In 1642 he was made doctor of divinity at Oxford; near which place he sheltered himself during the time of the rebellion; but after the restoration returned to his archdeaconry, where he died in 1661. His works are, 1. Twenty sermons, published at different times. 2. *Philosophiæ politico-barbaræ specimen*, quarto. 3. Survey of the world, a poem in ten books, octavo. 4. A translation of the satires of Juvenal and Persius. 5. *Technogamia*, or the marriage of the arts, a comedy.

HOLINESS, or **SANCTITY**; a quality which constitutes or denominates a person or thing *holy*; i. e. pure, or exempt from sin. The word is also used in respect of persons and things that are sacred, i. e. set apart to the service of God, and the uses of religion.

HOLINESS, is also a title or quality attributed to the pope; as that of *majesty* is to kings. Even kings, when writing to the pope, address him under the venerable appellation of *Your Holiness*, or *Holy Father*; in Latin, *Sanctissime* or *Beatissime Pater*. Anciently the same title was given to all bishops. The Greek emperors also were addressed under the title of *Holiness*, in regard of their being anointed with holy oil at their coronation. De Cange adds, that some of the kings of England have had the same attribute; and

Holinshed that the orientals have frequently refused it to the pope.

Holland

HOLINSHED (Raphael), an English historian famous for the *Chronicles* under his name, was descended from a family that lived at Bosely in Cheshire; but neither the time of his birth, nor scarcely any circumstances of his life, are known. However, he appears to have been a man of considerable learning, and to have had a genius particularly adapted for history. His *Chronicles of England, Scotland, and Ireland*, were first published at London in 1570, in 2 vols folio; and then in 1587, in 3 vols. In this second edition several sheets in the 2d and 3d vols were castrated for containing some passages disagreeable to queen Elizabeth and her ministers; but the castrations have since been printed apart. Holinshed was not the sole compiler of this work, being assisted in it by several other hands. The time of his death is unknown; but from his will, which is prefixed to Hearne's edition of *Cambden's Annals*, it appears to have happened between 1578 and 1582.

HOLLAND (Philemond), M. D. commonly called the Translator general of his age, was educated in the university of Cambridge. He was for many years a schoolmaster at Coventry, where he also practised physic. He translated Livy, Pliny's Natural History, Plutarch's *Morals*, Suetonius, Ammianus Marcellinus, Xenophon's *Cyropædia*, and Cambden's *Britannia*, into English; and the geographical part of Speed's *Theatre of Great Britain* into Latin. The *Britannia*, to which he made many useful additions, was the most valuable of his works. It is surprising, that a man of two professions could find time to translate so much; but it appears from the date of the *Cyropædia*, that he continued to translate till he was 80 years of age. He died in 1636, aged 85. He made the following epigram upon writing a large folio with a single pen:

With one sole pen I wrote this book,
Made of a grey goose quill;
A pen it was when it I took,
And a pen I leave it still.

HOLLAND, the largest of the seven United Provinces, divided into South and North Holland, the latter of which is also called *West Friesland*, is bounded on the west by the German ocean, or north sea; to the east by the Zuyder-see, the province of Utrecht, and part of Gelderland; to the south by Dutch Brabant and Zealand; and to the north by the Zuyder-see. Its greatest extent from north to south, including the island of Texel, is about 90 English miles; but from east to west its extent varies from 40 to 25. To defend it against the sea, dykes have been erected at an immense expence, and innumerable canals cut to drain it, as being naturally very low and marshy. Some parts of the province are very fruitful in corn; but the greater parts consist of rich pastures, wherein are kept large herds of kine, which supply them with incredible quantities of butter and cheese. Of the latter, that of Edam, in North Holland, is highly esteemed. The many rivers and canals that intersect the province are of great advantage to its commerce, but contribute to render the air foggy and unwholesome. There is a communication by water betwixt almost every town and

village. Towards the middle also of the province are great numbers of turf pits. It is so populous, that the number of the inhabitants is computed at 1,200,000. In point of cleanliness no country surpasses, and few come up to it, especially in North Holland, and that even in the villages. From the counts of Holland this province devolved, in 1436, to the dukes of Burgundy, and from them to the house of Austria, along with the other provinces. The States of Holland and West Friesland are composed of the nobility and deputies of the towns; of the latter there are 18 that send deputies to the assembly of the states, which is held at the Hague. The grand pensionary is a person of great dignity and weight in this assembly, and his office requires extraordinary abilities. There are also two councils composed of deputies, one for South, and another for North Holland, who have the cognizance of the revenue and military affairs. The whole province sends one deputy from among the noblesse to the states-general, who takes precedence of all others, together with three or four more. There are two supreme courts of judicature for Holland and Zealand; viz. the great council of Holland and Zealand, and the hof or court of Holland. To these appeals lie from the towns; but the causes of noblemen come before them in the first instance. With respect to the ecclesiastical government, there is a synod held annually both in South and North Holland, of which the former contains eleven classes, and the latter six; and the ministers of both together amount to 331. In the whole province are 37 towns, 8 boroughs, and 400 villages.—For the history, see UNITED PROVINCES.

HOLLAND, one of the divisions of Lincolnshire in England. It so much resembles the province of that name upon the continent, in most respects, being low and marshy, with the sea on one side, and canals running through it, that it must either have had its name from thence, or on the same account. On the east it has what the ancient geographers call *Æstuarium Metaris*, now the Washes, which are overflowed at high water, and part of Cambridgeshire on the south. The lower part of it is full of bogs and marshes, and has huge banks to defend it against the sea and land floods. The ground is so soft, that horses are worked unshod; and it produces plenty of grass, but little corn. The whole tract seems to have been gained from the sea; and is divided into Upper and Lower, the latter of which was unpassable; but since the fens have been drained, the lands are grown more solid, and the inhabitants sow cole-seed upon them to their great profit. Though there are no stones to be found in or upon the ground, yet most of the churches are of stone. They have no fresh water but from the clouds, which is preserved in pits: but if these are deep, it soon turns brackish; and if they are shallow, they soon become dry.

New HOLLAND, the largest island in the world, reaching from 10 to 44 deg. S. Lat. and between 110 and 154 of E. long. from London. It received its name from having been chiefly explored by Dutch navigators. The land first discovered in those parts, was called *Eendragt* (Concord) Land, from the name of the ship on board which the discovery was made, in 1616; 24 deg. and 25 deg. south. In 1618, another part of this coast, nearly in 15 deg. south, was discovered.

Holland,
New Hol-
land.

New Hol-
land.

discovered by Zeachen, who gave it the name of *Arnheim* and *Diemen*; though a different part from what afterwards received the name of *Diemen's Land* from *Tasman*, which is the southern extremity, in latitude 43 deg. In 1619, Jan Van Edels gave his name to a southern part of New Holland. Another part, situated between 30 and 33 deg. received the name of *Leuwen*. Peter Van Nultz gave his name, in 1627, to a coast which communicates to *Leuwen's Land* towards the westward; and a part of the western coast, near the tropic of Capricorn, bore the name of *De Wits*. In 1628, Peter Carpenter, a Dutchman, discovered the great gulph of *Carpentaria*, between 10 and 20 deg. south. In 1687, Dampier, an Englishman, sailed from Timor, and coasted the western parts of New-Holland. In 1699, he left England, with a design to explore this country, as the Dutch suppressed whatever discoveries had been made by them. He sailed along the western coast of it, from 28 to 15 deg. He saw the land of *Endraght* and of *De Wit*. He then returned to Timor: from whence he went out again; examined the isles of *Papua*; coasted *New-Guinea*; discovered the passage that bears his name; called a great island which forms this passage or strait on the east side, *New Britain*; and sailed back to Timor along *New-Guinea*. This is the same Dampier who, between 1683 and 1691, sailed round the world by changing his ships. Notwithstanding the attempts of all these navigators, however, the eastern part of this vast tract was totally unknown till Captain Cook made his late voyages; and by fully exploring that part of the coast, gave his country an undoubted title to the possession of it; which accordingly has since been taken possession of under the name of *New South Wales*.

I
Whether
the name
of continent
belongs to
New Hol-
land.

Some have disputed whether the title of *island* can be properly applied to a country of such vast extent, or whether it ought not rather to be denominated a *continent*; while others have replied, that though the

word *island*, and others similar to it, do indeed signify a tract of land surrounded by sea, yet in the usual acceptance it means only a land of moderate extent surrounded in this manner. Were it otherwise, we might call the whole world an island, as it is every where surrounded by the sea; and in fact, *Dionysius Perigetes* applies this term to it, with the addition of the word *immense*, to distinguish it from other islands. The best rule, according to Mr Stockdale, for determining when a country ought to lose the name of *island* and begin to be called a *continent*, is when it begins to lose the advantages of an insular situation. The first and principal of these, is the being capable of an union under one government, and thence deriving a security from all external attacks excepting those by sea; but in countries of great extent, this is not only difficult, but impossible. If we consider, therefore, *New Holland* as extending about a thousand miles every way, we shall find that its claim to be called a continent is undoubted; its length from east to west being about 2400 English miles, and 2300 from north to south.

This coast was first explored by Captain Cook in the year 1770; but his stay was too short to examine the nature of the country with the accuracy which he would otherwise have done had he continued longer in it. In general, it was found rather barren than otherwise. Many brooks and springs were found along the eastern coast, but no river of any consequence. They found only two kinds of trees useful as timber, the pine, and another which produces a sort of gum. They found three kinds of palm-trees; but few esculent plants, though there are abundance of such as might gratify the curiosity of the botanist. A great variety of birds were met with, which have since been particularly described; but the number of quadrupeds bears but a very small proportion to that of the other animals. The most remarkable insects seen at this time were the green ants (A), who build their nests upon trees in a very singular manner.

land.

2
Captain
Cook's ac-
count of
the coun-
try.

This

(A) These little animals form their habitations, by bending down the leaves of trees, and gluing the ends of them together so as to form a purse. Though these leaves are as broad as a man's hand, they perform this feat by main strength, thousands of them being employed in holding down the leaves, while multitudes of others apply the glutinous matter. Captain Cook's people ascertained themselves that this was the case, by sometimes disturbing them at their work; in which case the leaf always sprung up with an elasticity which they could not have supposed that such minute insects were capable of overcoming. For this curiosity, however, they smarted pretty severely; for thousands of these little enemies instantly threw themselves upon the aggressors, and revenged themselves by their bites or stings for the interruption they had met with. These were little less painful at first than the sting of a bee; but the pain did not last above a minute. Another species of ants burrow themselves in the root of a plant which grows on the bark of trees like the mistletoe, and which is commonly as big as a large turnip. When this is cut, it appears intersected with innumerable winding passages all filled with these animals; notwithstanding which, the vegetation of the plant suffers no injury. These do not give pain by their stings, but produce an intolerable itching by crawling about on the skin. They are about the size of the small red ant in this country. Another sort, which do not molest in any manner, resemble the white ants (see *TERMES*) of the East Indies. They construct nests three or four times as big as a man's head on the branches of trees; the outsides being composed of some vegetable matter along with a glutinous substance. On breaking the outer crusts of these hives, innumerable cells appear swarming with inhabitants, in a great variety of winding directions, all communicating with each other, and with several other nests upon the same tree. They have also another house built on the ground, generally at the root of a tree; formed like an irregularly sided cone; sometimes more than six feet high, and nearly as much in diameter. The outside of these is of well-tempered clay about two inches thick; and within are the cells, which have no opening outward. One of these is their summer and the other their winter dwelling, communicating with each other by a large avenue leading to the ground, and by a subterraneous passage. The ground structures are proof against wet, which those on the branches are not.

land.

³
Settlement
of a British
colony in
New Hol-
land.

This country has now become an object of more consequence than formerly, by reason of the establishment of a British colony in it; where the criminals condemned to be transported are sent to pass their time of servitude. Before this plan was resolved on by government, another had been discussed, *viz.* that of employing these criminals in workhouses; and Judge Blackstone, with Mr Eden and Mr Howard, had considered of the best method of putting it in execution: but though this plan had been approved by parliament as early as 1779, some difficulties always occurred, which prevented its going forward; and at length, on the 6th of December 1786, orders were issued by his majesty in council for making a settlement on New Holland, establishing a court of judicature in the colony, and other regulations necessary on the occasion. The whole received the complete sanction of legislature in the beginning of the year 1787. The squadron appointed for putting the design in execution began to assemble at the Mother Bank, the place of rendezvous, in the Isle of Wight, on the 16th of March 1787. It consisted of the Sirius frigate Captain John Hunter, the Supply armed tender Lieutenant H. L. Ball; three store-ships, the Golden-grove, Fishburn, and Borrowdale, for carrying provisions and stores for two years; and lastly, six transports, the Scarborough and Lady Penrhyn from Portsmouth, the Friendship and Charlotte from Plymouth, and the Prince of Wales and Alexander from Woolwich. These were to carry the convicts, with a detachment of marines in each proportioned to the nature of the service; the largest where resistance was most expected, *viz.* in those which carried the greatest number of male convicts. On the arrival of Governor Phillip at the station, he hoisted his flag on board the Sirius as commodore of the squadron; and the embarkation being completed, he gave the signal to weigh anchor on the 13th of May at day-break. The number of convicts was 778, of whom 558 were men. They touched at the island of Teneriffe on the 3d of June, without meeting with any bad accident. Here they staid a week, in order to procure such refreshments as were necessary for preventing the disorders mostly to be dreaded in such a long and perilous voyage. In this they succeeded to their wish; and were about to depart on the 9th of June, when it was discovered that one of the convicts had made his escape, having found means to cut away a boat and make off with it. He offered himself as a sailor aboard a Dutch vessel at that time in the harbour, but was refused; on which he attempted to conceal himself in a cove. In this he would probably have succeeded, had it not been for the boat which he could not conceal; so that he was soon discovered and brought back to the ship, where, however, he obtained his pardon from the governor.

On the 10th of June the fleet set sail from Santa Cruz in the island of Teneriffe, and on the 18th came in sight of the Cape Verd islands, where they steered for St Jago: but the want of a favourable wind and other circumstances prevented their getting in; so that as Governor Phillip did not chuse to waste time, they did not touch land till they came to Rio Janeiro on the coast of Brasil. It may seem surprising, that a voyage to the eastward, which of itself may be accounted of sufficient length, should thus be wilfully made so much

longer, by sailing twice across the Atlantic. The calms, however, so frequent on the coast of Africa, seem of themselves to be a sufficient inducement for navigators to preserve a westerly course; and even the islands at which it is so necessary to touch, are not far distant from the American coast. The returning tracks of Captain Cook's three voyages are all within a little space of the 45th degree of west longitude, which is even 10 degrees farther west than Cape St Roque; and that course appears to have been taken voluntarily, without any extraordinary inducement.

During the time of their stay at Santa Cruz the weather had been very moderate; the barometer about 30 inches, and the thermometer never above 72; as they approached the Cape Verd islands it rose to 82, and did not exceed 82° 51' all the way from thence to Rio Janeiro. Here they met with a very favourable reception, contrary to that which Captain Cook experienced on a similar occasion. Provisions were so cheap, that though the allowance of meat was fixed by the governor at 20 ounces per day, the men were victualled completely at 3^d each, including rice, vegetables, and every other necessary. Wine was not at this time to be had except at an advanced price: but rum was laid in, and such seeds and plants procured as were thought most likely to flourish in New South Wales; particularly coffee, indigo, cotton, and the cochineal fig. An hundred sacks of cassada were likewise purchased as a substitute for bread, if it should happen to be scarce. By the kindness of the viceroy also, some deficiencies in the military stores were made up from the royal arsenal, and every assistance given which the place could afford. They arrived here on the 5th of August 1787, and set sail on the 4th of September, receiving as the last compliment from the governor a salute of 21 guns.

From Rio de Janeiro the fleet had a fine run to Table Bay, in the southern extremity of Africa, which they accomplished in 39 days; where they took in the refreshments meant to supply them during the remainder of the voyage. Here they arrived on the 13th of October; and having supplied themselves with a great number of live stock, they set sail on the 12th of November, but were long impeded by contrary winds from the southeast. On the 25th they were only 80 leagues distant from the Cape, when Governor Phillip left the Sirius and went aboard the Supply tender; in hopes, by leaving the convoy, to gain sufficient time for examining the country round Botany Bay, that the most proper situation for the new colony might be chosen before the transports should arrive. They now met with favourable winds, blowing generally in very strong gales from the northwest, west, and southwest. The wind shifted only once to the east, but did not continue in that direction above a few hours. On the 3d of January 1788 the Supply came within sight of New South Wales; but the winds then became variable, and a current, which at times set very strongly to the southward, impeded her course so much, that it was not till the 18th of the month that she arrived at Botany Bay.

Governor Phillip no sooner landed than he had an opportunity of conversing with the natives, who were assembled on shore. As it was the intention of this gentleman to conciliate if possible their friendship, he used every method at this first interview to inspire them with a favourable idea of the Europeans. For this purpose

pose he presented them with beads and other trifling ornaments, which they seemed pleased to wear, though Captain Cook found them very indifferent about any kind of finery he could furnish them with. They seemed, according to the account of that celebrated navigator, to be so attached to their own ornaments, that they made no account of any thing else. They received indeed such things as were given them, but made no offer to return any thing in exchange; nor could they be made to comprehend that any thing of the kind was wanted. Many of the presents which they had received were found afterwards thrown away in the woods.

6
Inconveni-
ence of Bo-
tany Bay
for a settle-
ment.

Governor Phillip having parted with his new acquaintance in a friendly manner, next set about an examination of the country about Botany Bay, which had been strongly recommended by Captain Cook as the most eligible place for a settlement. He found, however, that the bay itself was very inconvenient for shipping; being exposed to the easterly winds, and so shallow that ships even of a moderate burden could not get far enough within land to be sheltered from the fury of the ocean. Neither did the land about any part of this bay appear an eligible situation for a colony; being in some places entirely swampy, in others quite destitute of water. Point Sutherland seemed to afford the situation most free from objections, but the ships could not approach it; and even here the ground seemed to be universally damp and spongy: so that, on the whole, finding no place within the compass of the bay proper for the new settlement, they found themselves obliged to remove somewhere else.

The rest of the fleet arrived in two days after the Supply; and that no time might be lost, Governor Phillip ordered the ground about Point Sutherland to be cleared, and preparations to be made for landing, while he went with several officers in three boats to examine Port Jackson, which was only three leagues distant. Here they had the satisfaction to find one of the finest harbours in the world, where 1000 sail of the line might ride in perfect safety. On examining the different coves, one was preferred which had a fine run of spring water, and where ships could anchor so close to the shore, that at a very small expence quays might be constructed for loading and unloading the largest vessels. This was named by the governor *Sydney Cove*, in honour of Lord Sydney, and the country around it destined for the place of settlement. It is about half a mile long, and a quarter of a mile broad at the entrance. On the governor's return to Botany Bay, the reports made to him concerning the adjacent country were so exceedingly unfavourable, that orders were immediately given for the removal of the fleet to Port Jackson. On the morning of the 25th, therefore, the governor sailed from Botany Bay, and was soon followed by the whole fleet. In the mean time, they were surprised by the appearance of two other European vessels, which had been first seen off Botany Bay on the 24th. These were found to be two French ships, named the *Astrolabe* and *Bouffola*, which had left France on a voyage of discovery under the command of M. la Peyrouse, in the year 1785. They had touched at the island of Santa Catharina on the coast of Brasil, and from thence gone by the extremity of South America into the Pacific Ocean, where they had

7

ment form-
ed at Port
Jackson.8
Visited by
two French
ships.

run along by the coasts of Chili and California; after which they had visited Easter Island, Nootka Sound, Cook's river, Kamtschatka, Manilla, the Isles des Navigateurs, Sandwich, and the Friendly Isles. They had also attempted to land on Norfolk Island, but found it impossible on account of the surf. During the whole voyage none were lost by sickness; but two boats crews had unfortunately perished in a surf on the northwest coast of America; and at Masfuna, one of the *Isles des Navigateurs*, M. L'Angle, captain of the *Astrolabe*, with 12 of his people, officers and men, were murdered by the savages. This was the more surprising, as there had been an uninterrupted friendship with them from the time the French touched at the island, till that unfortunate moment M. L'Angle had gone ashore with two long boats for the purpose of filling some water-casks. His party amounted to 40 men; and the natives, from whom the French had already received abundance of refreshments, did not show any signs of an hostile disposition: But from whatever motive their resentment was excited, the men had no sooner begun to get out the boats, than the savages made a most furious and unexpected assault with stones. In this encounter M. L'Angle himself, with the people above mentioned, fell a sacrifice to the treachery of these barbarians. The remainder of the party escaped with great difficulty; the ships having at that time passed a point of land which intercepted their view of the affray.

The convicts and others destined to remain in New South Wales being landed, no time was lost in beginning to clear ground for an encampment, store-houses, &c. The work, however, went on but slowly, partly owing to the natural difficulties they had to encounter, and partly owing to the habitual indolence of the convicts, which indeed was naturally to be expected considering their former way of life. Nevertheless, by the end of the first week of February, the plan of an encampment was formed, and places were marked out for different purposes, so that the colony already began to assume some appearance of order and regularity. The materials and frame-work of a slight temporary habitation for the governor had been brought out from England ready formed, which were landed and put together with as much expedition as circumstances would allow. Hospital tents were also erected; and the sickness which soon took place showed the propriety of so doing. In the passage from the Cape there had been but little sickness, and few of the convicts had died; but a little time after they landed a dysentery began to prevail, which proved fatal in several instances, and the scurvy began to rage with great violence, so that the hospital-tents were soon filled with patients. The disorder proved the more virulent as fresh provisions could but rarely be obtained; nor were esculent vegetables often obtained in such plenty as could produce any material alleviation of the complaint: the only remedy for the dysentery was found to be a kind of red gum, produced in plenty by the trees growing upon this coast. The yellow gum has the same properties, though in an inferior degree.

In the beginning of February, a most violent storm of thunder and lightning destroyed five of the sheep which had a shed erected for them under a tree, which proved a prelude to other misfortunes among the cattle. The encampment, however, was carried on with great alacrity;

New Hol-
land.9
Regular
form of
govern-
ment esta-
blished.

alacrity; the foundations of the store-houses were laid, and every thing began to wear a promising appearance. On the 7th of the month a regular form of government was established in the colony, with all the solemnity which could possibly be given: the governor made a proper speech to the convicts, reminding them of the situation in which they stood; and that now, if they continued their former practices, it was impossible they could hope for mercy if detected; neither could they expect to escape detection in so small a society. Offenders, therefore, he said, would certainly be punished with the utmost rigour; though such as behaved themselves in a proper manner, might always depend upon encouragement. He particularly noticed the illegal intercourse betwixt the sexes, as a practice which encouraged profligacy in every respect; for which reason he recommended marriage: and this exhortation seemed not to be altogether in vain, as 14 marriages were celebrated that very week in consequence.

Heavy rains took place during the remainder of this month, which showed the necessity of going on with the work as soon as possible. The want of carpenters, however, prevented this from being done so expeditiously as could have been wished. Only 16 of these could be hired from all the ships; and no more than 12 of the convicts were of this profession, of whom several were sick; so that the party were by far too few for the work they had to perform. An hundred convicts were added as labourers; but with every effort it was found impossible to complete either the barracks or the huts for the officers as soon as could be wished. On the 14th of February a small party was sent out to settle on Norfolk Island, who have since established a colony there which promises to be of considerable utility†. It was soon found, however, absolutely necessary to make examples of some of the convicts at Port Jackson. Towards the end of February it was found necessary to convene a criminal court, in which six of the convicts received sentence of death. One who was the head of the gang was executed the same day; one of the rest was pardoned; the other four were reprieved, and afterwards exiled to a small island within the bay, where they were kept on bread and water. They had frequently robbed both the stores and other convicts. The fellow who was executed, and two others, had been detected in stealing the very day on which they received a week's provision; and at the same time that their allowance was the same as that of the soldiers, spirituous liquors only excepted.

11
Broken
Bay exam-
ined.

In the beginning of March the governor went out with a small party to examine Broken Bay, lying about eight miles to the northward of Port Jackson. This was found very extensive, with many openings. One of the latter ended in several small branches, and a large lagoon, which they could not at that time examine. Most of the land about the upper part of this branch was low and full of swamps, with great numbers of pelicans, and other aquatic birds. Among the rest they met with an uncommon bird called at that time the *Hooded Gull*, but afterwards found to be the species named by Mr Latham the *Caspian Tern*.

From this northwest branch they proceeded across the bay to the southwest branch, which is also very extensive, with a second opening to the westward capable of affording shelter to almost any number of

Nº 156.

ships, with depth of water for vessels of almost any burden. The land was found much higher here than at Port Jackson, more rocky, and equally covered with timber. Large trees were seen growing even on the summits of the mountains, which appeared totally inaccessible to the human species. Round the headland which forms the southern entrance into the bay is a third branch, which governor Phillip thought the finest piece of water he had ever seen; which for that reason he honoured with the name of *Pit-water*. This branch, as well as the former, is sufficient to contain all the navy of Great Britain; but the latter has a bar at the entrance of only 18 feet at low water. Within are from 7 to 15 fathoms. The land here is more level than on the southwest branch, and some situations are proper for cultivation. The governor determined to have returned by land, in order to explore the country betwixt Port Jackson and Broken Bay, but the continual rains prevented him.

On the 10th of March the French ships departed, little intercourse having passed between them and the English during the time of their stay. While the former remained in Botany Bay, Father la Recheur, who had come out in the *Astrolabe* as a naturalist, died of the wounds he had received in the battle with the inhabitants of Masuna. A kind of monument was erected to his memory, with the following inscription:

Hic jacet LE RECHEUR
E. F. F. minimis Galliae sacerdos,
Physicus in circumnavigatione
Mundi

Duce DE LA PEYROUSE,
Ob. 17th, Feb. 1788.

This monument, however, was soon after destroyed by the natives; on which Governor Phillip caused the inscription to be engraved on copper and nailed to a neighbouring tree. M. de la Peyrouse had paid a similar tribute to the memory of Captain Clerke at Kamtschatka.

On the 15th of April, the governor, attended by several officers and a small party of marines, set out on an expedition into the interior parts of the country. Their first landing was at the head of a small cove named *Shell-cove*, near the entrance of the harbour on the north side. Proceeding in this direction, they arrived with great labour at a large lake surrounded on all sides with bog and marshy ground to a considerable extent, and in which they frequently plunged up to the waist. Here they observed that bird so rare in other parts of the world, viz. a black swan. On being fired at, it rose, and showed that its wings were edged with white, the bill being tinged red. They spent three days in a very laborious manner in passing the marshes and swamps which lie in the neighbourhood of the harbour: and here they had an opportunity of observing, that all the small streams which descend into Port Jackson proceed from swamps, occasioned by the stagnation of the water in the low grounds as it rises from the springs. On leaving these low grounds, they found them succeeded by a rocky and barren country; the hills covered with various flowering shrubs, though frequently inaccessible by reason of various natural obstacles. At about 15 miles distance from the sea, the governor had a fine view of the internal parts of the country, which were mountainous.

New Hol-
land.

To the most northerly chain of these he gave the name of *Carmarthen*, and to the most southerly that of *Lansdown, Hills*; and to one which lay between these he gave the name of *Richmond Hill*. It was conjectured, that a large river must rise from these mountains; but there was now a necessity for returning. On the 22d, however, another expedition was undertaken. Governor Phillip with his party landed near the head of the harbour. Here they found a good country; but in a short time arrived at a close thicket through which they found it impossible to make their way, so that they were obliged to return. Next day, by keeping close to the banks of a small creek, they made a shift to pass that obstacle, and continued their course for three days to the westward. The country was now extremely fine, either entirely level or rising in small hills, the soil excellent, but stony in a few places. The trees grew at the distance of from 20 to 40 feet from each other, in general totally destitute of under-wood, which was confined to the barren and stony spots. On the 5th day they saw for the first time in this second expedition *Carmarthen* and *Lansdown hills*; but the country all round was so beautiful, that Governor Phillip gave it the name of *Belle vue*. They were still apparently 30 miles from the mountains which they had intended to reach; but not having been able to carry more than six days provisions along with them, they found it necessary to return; and even with this small flock the officers as well as men were obliged to carry heavy loads. During all this time they had not proceeded farther in a direct line than 30 miles, so great were the obstructions they had met with from deep ravines, &c. Their return, however, was effected with much greater ease, having cleared a track, and marked trees all the way as they went along to direct them in their journey back. The country explored at this time appeared so fine, that Governor Phillip determined to form a settlement there as soon as a sufficient number could be spared from those works which were immediately necessary. On his return he had the mortification to find, that five ewes and a lamb had been killed very near the camp, and in the middle of the day. This mischief was supposed to have been done by some dogs belonging to the natives.

All this time the scurvy had continued to rage with great violence; so that by the beginning of May near 200 people were incapable of work. For this reason, and on account of the great difficulty of clearing the ground, no more than eight or ten acres of wheat and barley had been sown, besides what private individuals had sown for themselves; and it was even feared that this small crop would suffer from the depredations of ants and field-mice. To procure as much relief as possible therefore in the present exigence, the Supply was sent in the beginning of May to Lord Howe Island in hopes of procuring some turtle and other provisions; but unfortunately the vessel returned without any turtle, having met with squally weather, and being obliged to cut away her best bower anchor. The natives now began to show an hostile disposition which they had not hitherto done. One of the convicts, who had wandered away from the rest in quest of vegetables, returned with a very dangerous wound in the back; giving information also, that another who had gone out for the

14
Murders
committed
by the na-
tives.

VOL. VIII. Part II.

same purpose had been carried off in his fight by the natives, after being wounded in the head. A shirt and hat were afterwards found in some of the huts of the natives, but no intelligence of the man could be gained. This was followed by other misfortunes of the same nature. On the 30th of the month, two men who had been employed in cutting rushes for thatch at some distance from the camp were found dead. One of them had four spears in his body, one of which had pierced quite through it; but the other had no marks of violence upon him. In this case, however, it was proved, that those who suffered had been the aggressors; as they had been seen with one of the canoes of the natives which they had taken from one of the fishing places. All possible inquiry was made after the natives who had been guilty of the murder, but to no purpose. In the course of this inquiry, it was found that one of the natives had been murdered, and several wounded, previous to the attack upon the rush-cutters. The governor promised liberty to any convict who should discover the aggressors; but no information was procured, though it is probable that it may prevent accidents of that kind for the future. About this time the two bulls and four cows belonging to government and to the governor, having been left for some time by the man who had the charge of them, strayed into the woods and could not be recovered, though they were afterwards traced to some distance.

The 4th of June being his majesty's birth-day, was celebrated with as much festivity as circumstances would allow; and on this occasion it was first made public that the governor had given the name of *Cumberland County* to this part of the territory. The appointed boundaries were *Carmarthen* and *Lansdown hills* on the west, the northern parts of *Broken Bay* on the north, and the southern parts of *Botany Bay* on the south; thus including these three principal bays, with *Sydney Cove* nearly in the centre.

The misfortunes which attended those convicts who strayed to too great a distance from the settlement, were not sufficient to prevent some of them from rambling into the woods, in hopes of subsisting themselves there and regaining their liberty. One of these, who had been guilty of a robbery, fled into the woods on the 5th of June, but was obliged to return half-starved on the 24th. He had found it impossible to subsist in the woods, and had met with very little relief from the natives. One of them gave him a fish, but made signs for him to go away. According to his account, they themselves were in a very miserable situation; and he pretended to have seen four of them apparently dying of hunger, who made signs to him for something to eat. He pretended also to have fallen in with a party who would have burnt him, and that he made his escape from them with difficulty. He said also, that he had seen the remains of a human body lying on a fire; and endeavoured to inculcate the idea of these savages eating human flesh when other provisions were scarce. This poor wretch was tried and executed for the theft he had committed before his departure, along with another criminal.

By this time the colony was so far advanced, that the plan of a regular town had been marked out. The principal street, when finished, is to be 200 feet wide, terminated by the governor's house, the main guard, and

15
A convict
executed.

16
Regular
town laid.

New Hol-
land.

and criminal court. The plans of other streets are likewise marked out; and it is the governor's intention, that when houses are built here, the grants of land shall be made with such clauses as will prevent the building of more than one house on one allotment, which is to consist of 60 feet in front and 150 in depth. Thus a kind of uniformity will be preserved in the building, narrow streets prevented, and many inconveniences avoided, which a rapid increase of inhabitants might otherwise occasion. It has likewise been an object of the governor's attention to place the public buildings in such situations as will be eligible at all times, and particularly to give the storehouses and hospital sufficient space for future enlargement, should it be found necessary. The first huts erected in this place were composed only of the soft wood of the cabbage palm, in order to give immediate shelter, and which had the further inconvenience of being used quite green. The huts of the convicts were constructed only of upright posts wattled with slight twigs, and plastered up with clay. Buildings of stone might easily have been raised, had there been any means of procuring lime for mortar. There were three kinds of stone met with about Sydney Cove, one equal in goodness to Portland stone, an indifferent kind of sand stone or firestone, and a sort which seems to contain iron; but neither chalk nor any species of limestone have yet been discovered. Lime was indeed procured from oyster-shells collected in the neighbouring coves to construct a small house for the governor; but it cannot be expected that a sufficient quantity can thus be procured for many or very extensive buildings. Good clay for bricks has been found near Sydney Cove, and very good bricks have been made of it; the wood also, notwithstanding the many reports to the contrary, is found abundantly fit for various purposes after being thoroughly seasoned. Such specimens as have been sent to England were fine-grained and free of knots, but heavy.

On the point of land that forms the west side of the Cove a small observatory has been erected, the longitude of which has been ascertained to be $159^{\circ} 19' 30''$ east from Greenwich, and the latitude $32^{\circ} 52' 30''$ south. Instead of thatch they now make use of shingles made from a certain tree, which has the appearance of a fir, but produces wood like English oak.

17
Different
accounts of
the colony.

With regard to the state of this colony there have been various and discordant accounts. Some of these have represented the country in such a light, that it would seem impossible to subsist on it; and it has been said, that the people who have had the misfortune to go there already were in the utmost danger of starving before any assistance could be sent from Britain. These reports, however, appear not to be well-founded. Difficulties must undoubtedly be felt at the first settlement of every uninhabited country; and we are not to expect that a colony, most of whom are wretches exiled for their crimes from their own country, can thrive in an extraordinary manner for some time. It appears, indeed, that so far from the transportation to this place having had any good effect in reforming them, the governor has been obliged to execute the utmost rigour of the law by hanging several of them. A good number of others have unaccountably disappeared, and are supposed to have been murdered by

the natives, or perished with hunger in the woods; so that, unless the numbers be recruited by more respectable inhabitants, it is not likely that much can be expected from the Port Jackson settlement for a long time to come. Of this, however, there seems to be little doubt: the general spirit of emigration which prevails through most, indeed we may say all the countries of Europe, will undoubtedly soon supply a sufficient number; and even some of the Americans, notwithstanding the extent and fertility of their own country, and the liberty they enjoy in it, are said to be willing to exchange these blessings for the precarious hopes of what may be obtained in New Holland among British convicts and slaves. This rambling disposition may perhaps be accounted for from an observation which has been made, viz. that "it may admit of a doubt whether many of the accommodations of a civilized life be not more than counterbalanced by the artificial wants to which they give birth. That these accommodations do not give a satisfaction equivalent to the trouble with which they are procured, is certain; and it is no wonder, then, to find numbers of people in every country who are willing to exchange them for independent ease and tranquillity, which belong, comparatively speaking, to few individuals in those countries which are called civilized."

With regard to the geography of this extensive country, which may perhaps be reckoned a fifth general division of the world, Captains Cook and Furneaux so fully explored its coasts, that succeeding navigators have added nothing to their labours. The only part which still remains unknown is that between the latitudes of $37^{\circ} 58'$ and 39° south; and as none of the fleet which lately sailed from Britain could be supposed to undertake any voyage of discovery, it is unknown whether or not a strait intersects the continent in this place or not. Captain Tench, however, informs us, on the authority of a naval friend, "that when the fleet was off this part of the coast, a strong set-off shore was plainly felt."

A vast chain of lofty mountains run nearly in a north and south direction farther than the eye can trace, about 60 miles inland. The general face of the country is pleasing, diversified with gentle risings and small winding valleys, covered for the most part with large spreading trees, affording a succession of leaves in all seasons. A variety of flowering shrubs, almost all entirely new to an European, and of exquisite fragrance, abound in those places which are free from trees; and among these, a tall shrub, bearing an elegant flower, which smells like English may, is peculiarly delightful, and perfumes the air to a great distance. There are but few trees; and, as Captain Tench and others relate, of so bad a grain, that they can scarcely be used for any purpose: This, however, Mr Stockdale ascribes to their being used in an unseasoned state, as has been already mentioned. In return for these bad qualities, however, the trees yield vast quantities of the gum already mentioned as a cure for the dysentery. It is of an acrid quality, and therefore requires to be given along with opiates. The tree which yields it is of very considerable size, and grows to a great height before it puts out any branches. The gum itself is usually compared to *sanguis draconis*, but differs from it in being perfectly soluble in water, which

New Hol-
land.

118

General ac-
count of the
country.

19

Red and
yellow
gums.

New Hol-
land.

which the sanguis draconis does not. It may be extracted from the wood by tapping, or taken out of the veins when dry. The leaves are narrow, and not unlike those of a willow; the wood fine grained and heavy, but warps to such a degree, when not properly seasoned, as soon to become entirely useless.

The yellow gum is properly a resin, being entirely insoluble in water. It greatly resembles gamboge, but has not the property of staining. It is produced by a low small plant with long grassy leaves; but the fructification shoots out in a surprising manner from the centre of the leaves on a single straight stem to the height of 12 or 14 feet. This stem is strong and light, and is used by the natives for making their spears. The resin is generally dug up from the soil under the tree, not collected from it, and may perhaps be the same which Tasman calls *gum lac of the ground*. It has been tried by Dr Blanc physician to St Thomas's hospital, who found it very efficacious in the cure of old fluxes, and that in many and obstinate cases. Many of the New Holland plants have been already imported into Britain, and are now flourishing in perfection at the nursery gardens of Mr Lee of Hammer-smith.

The soil immediately around Sydney Cove is sandy, with here and there a stratum of clay; but hitherto the produce has not been remarkable. The principal difficulty hitherto experienced in cleaning the ground arises from the size of the trees, which is said to be so enormous, that 12 men have been employed for five days in grubbing up one. Captain Cook speaks of some fine meadows about Botany Bay, but none of these have been seen by the present settlers, and Governor Phillip supposes them to have been swamps seen at a distance. Grass grows in almost every place, but in the swamps with the greatest vigour and luxuriance, though not of the finest quality. It is found to agree better with cows and horses than sheep. A few wild fruits are sometimes procured; among which is a kind of small purple apple mentioned by Captain Cook; and a fruit which has the appearance of a grape, but tasting like a green gooseberry, and excessively sour.

20
Scarcity of
fresh wa-
ter.

From the first discovery of this continent, the extreme scarcity of fresh water has been mentioned by every navigator. None have been fortunate enough to enter the mouth of any navigable river such as might be expected in a country of such extent. The settlers about Port Jackson found enough for common purposes of life; but Captain Tench informs us, that when he left the country, towards the end of 1788, there had been no discovery of a stream large enough to turn a mill. Since that time, however, Governor Phillip has been more successful; as we are informed by a letter of his to Lord Sidney, of date Feb. 13. 1790: In this letter he relates, that soon after the ships sailed in November 1788, he again made an excursion to Botany Bay, where he staid five days; but the researches he made there tended only to confirm him in the opinion he already entertained that the country round it was by no means an eligible situation for a colony. After having visited Broken Bay several times with boats, a river was found, which has since been traced, and all those branches explored which afforded any depth of water. This river has

21
Rivers dis-
covered by
Captain
Phillip.

obtained the name of *Hawkesbury*, is from 300 to 800 feet wide, and seems navigable for the largest merchant ships as far up as Richmond hill, at which it becomes very shallow, and divides into two branches; on which account the governor calls Richmond Hill the head of the river. As after very heavy rains, however, the water sometimes rises 30 feet above its level, it would not be safe for ships to go up so far; but 15 or 20 miles below it they would lie in fresh water, and be perfectly safe.

The country about Broken Bay is at first high and rocky, but as we proceed up the river it becomes more level, the banks being covered with timber, and the soil a light rich mould, supposed to be very capable of cultivation. The other branches of this river are shallow, but probably run many miles up into the country. Great numbers of black swans and wild ducks were seen on these rivers, and the natives had several decoys for catching quails.

Richmond hill, near which a fall prevented the boats from proceeding farther up, is the most southerly of a large range of hills which run to the northward, and probably join the mountains nearly parallel to the coast from 50 to 60 miles inland. The soil of this hill is good, and it lies well for cultivation. There is a very extensive prospect from the top, the whole country around seeming a level covered with timber. There is a flat of six or seven miles between Richmond hill and a break in the mountains which separates Lansdown and Carmarthen hills; in which flat the governor supposes that the Hawkesbury continues its course; though the river could not be seen on account of the timber with which the ground is every where covered where the soil is good. Six miles to the southward of Port Jackson is a small river; and 20 to the westward is one more considerable, which probably empties itself into the Hawkesbury. As far as this river was at that time explored, the breadth was computed at from 300 to 400 feet. It was named the *Nepaan*, and, like the Hawkesbury, sometimes rises 30 feet above its level. A party who crossed the river attempted to reach the mountains, but found it impossible, probably for want of provisions. After the first day's journey they met with such a succession of deep ravines, the sides of which were frequently so inaccessible, that in five days they could not proceed farther than 15 miles. At the time they turned back, they supposed themselves to be 12 miles from the foot of the mountains. With regard to the state of the colony, it appears from this letter to be as flourishing as could in any reasonable manner be expected. Another has been formed at a place called Rosehill, at the head of the harbour of Sydney Cove. At this place is a creek, which at half flood has water for large boats to go three miles up; and one mile higher the water is fresh and the soil good. Some ground having been cleared and cultivated, the governor in the above letter writes, that 27 acres were got in: That the corn was exceedingly good; about 200 bushels of wheat and 60 of barley, with a small quantity of flax, Indian corn, and oats; all which is preserved for seed: That if settlers are sent out, and the convicts divided amongst them, this settlement will very shortly maintain itself; but without which this country cannot be cultivated to any advantage. "At

New Hol-
land

New Hol-
land.

present (continues the governor) I have only one person, who has about 100 convicts under his direction, who is employed in cultivating the ground for the public benefit, and he has returned the quantity of corn above mentioned into the public store: the officers have not raised sufficient to support the little stock they have: some ground I have had in cultivation will return about 40 bushels of wheat into store; so that the produce of the labour of the convicts employed in cultivation has been very short of what might have been expected, and which I take the liberty of pointing out to your lordship in this place; to show as fully as possible the state of this colony, and the necessity of the convicts being employed by those who have an interest in their labour." The country for 20 miles to the westward is very capable of cultivation; though the labour of cutting down the trees is very great. At Sydney Cove the stores had been infested by a swarm of rats which destroyed no less than 12,000 lb. weight of flour and rice. The gardens also had suffered very considerably; so that, having met with such a considerable loss of provision, and a sufficient supply not being procured from the Cape, governor Phillip thought proper to send a further detachment to Norfolk Island, where the fertility of the soil afforded great hopes of their being able in a short time to subsist themselves independent of any assistance from the stores.

22
Govern-
ment of the
colony.

With regard to the civil establishment in this colony, governor Phillip's jurisdiction extends from 45° 49' to 10° 37' south, being the northern and southern extremities of the continent. It commences again in 135° E. Long. from Greenwich; and proceeding in an easterly direction, includes all the islands within the above mentioned latitudes in the Pacific ocean; by which partition it is supposed that every source of litigation will be cut off, as all these are indisputably the discovery of the British navigators.

The powers of the governor are absolutely unlimited, no mention being made of a council to assist him in any thing; and as no stated time is appointed for assembling the courts similar to the assizes and gaol deliveries in England, the duration of imprisonment is altogether in his hands. He is likewise invested with a power of summoning general courts martial; but the insertion in the marine mutiny act, of a smaller number of officers than 13 being able to compose such a tribunal, has been neglected; so that a military court, should detachments be made from head quarters, or sickness prevail, may not always be found practicable to be obtained, unless the number of officers in the settlement at present be increased. The governor is allowed to grant pardons in all cases, treason and wilful murder excepted; and even in these he has authority to stay the execution of the law until the king's pleasure shall be signified. In case of the governor's death, the lieutenant governor takes his place; and on his decease, the authority is lodged in the hands of the senior officer.

It was not long after the convicts were landed that there appeared a necessity for assembling a criminal court; and it was accordingly convened by warrant from the governor. The members were the judge advocate, who presided, three naval, and three marine officers. The number of members is limited by act of parliament to seven; who are expressly ordered to be

officers either of his majesty's sea or land forces. The court being met, completely arrayed and armed as at a military tribunal, the judge advocate proceeds to administer the usual oaths taken by jurymen in England to each member; one of whom afterwards swears him in a like manner. This ceremony being over, the crime is laid to the prisoner's charge, and the question "guilty or not guilty" put to him. No law officer being appointed on the part of the crown, the party at whose suit he is tried is left to prosecute the prisoner entirely by himself. All the witnesses are examined on oath; and the decision must be given according to the laws of England, or "as nearly as may be, allowing for the circumstances and situation of the settlement," by a majority of votes, beginning with the youngest member, and ending with the president of the court. No verdict, however, can be given in cases of a capital nature, unless at least five of the seven members concur therein. The evidence on both sides being finished, and the prisoner's defence heard, the court is cleared, and, on the judgment being settled, is thrown open again, and sentence pronounced. During the time of sitting, the place in which it is assembled is directed to be surrounded by a guard under arms, and admission granted to every one who chuses to enter it. Of late, however, says captain Tench, our colonists are supposed to be in such a train of subordination, as to make the presence of so large a military force unnecessary; and two centinels in addition to the provost martial are considered as sufficient.

The first trials which came before this court were 23: Trials of those of three convicts, one of whom was convicted of having struck a marine with a cooper's adze, and of behaving otherwise in a most scandalous and riotous manner. For this he was condemned to receive 150 lashes, being a smaller punishment than a soldier would have suffered in a similar case. A second, for having committed a petty theft, was sent to a small barren island, and kept there on bread and water only for a week. The third was sentenced to receive 50 lashes; but being recommended by the court to the governor, had his sentence remitted. The same lenity, however, could not be observed in all cases. One fellow, who had been condemned to be hanged, was pardoned while the rope was about his neck, on condition that he would become the common executioner ever after. He accepted the horrid office, but not without a pause. Some examples of severity were undoubtedly necessary; and among these it is impossible to avoid feeling some regret for the fate of one who suffered death for stealing a piece of soap of eight pence value: but by the last letter of governor Phillip, we are informed that the convicts in general are now behaving much better; more so indeed than ever he expected. The last statement was of one woman who had suffered for a robbery; five children had died, and 28 been born. The whole amount of the deaths 77, of the births 87.

The number of convicts already sent to New South Wales amounts to 2000 and upwards—above 1800 are since embarked for that settlement. The annual expence of the civil and military establishments at that place is nearly L. 10,000.

Besides the criminal court, there is an inferior one composed of the judge advocate, and one or more justices

23:
Trials of
convicts,
&c.

New Hol-
land.New Hol-
land.24
Animals
found in
New Hol-
land.

justices of the peace, for the trial of small misdemeanors. This court is likewise empowered to decide all law-suits; and its verdict is final, except where the sum exceeds L. 300, in which case an appeal can be made to England from its decree. In case of necessity, an admiralty court, of which the lieutenant governor is judge, may also be summoned for the trial of offences committed on the high seas.

The quadrupeds on the continent of New Holland hitherto discovered are principally of the Opossum kind, of which the most remarkable is the Kangaroo. There is also a species of dogs very different from those known in Europe. They are extremely fierce, and never can be brought to the same degree of familiarity with those we are acquainted with. Some of them have been brought to England, but still retain their usual ferocity. There are a great many beautiful birds of various kinds; among which the principal are the black swans already mentioned, and the ostrich or cassowary; which last arrives frequently at the height of seven feet or more. Several kinds of serpents, large spiders, and scolopendras; have also been met with. There are likewise many curious fishes; though the finny tribe seem not to be so plentiful on the coast as to give any considerable assistance in the way of provisions for the colony. Some very large sharks have been seen in Port Jackson, and two smaller species, one named the Port Jackson shark, the other Watts's shark. The latter, notwithstanding its diminutive size, the mouth scarce exceeding an inch in breadth, is excessively voracious. One of them having been taken and flung down upon the deck, lay there quiet for *two hours*; after which Mr Watts's dog happening to pass by, the fish sprung upon it with all the ferocity imaginable, and seized it by the leg in such a manner that the animal could not disengage himself without assistance.

25
Climate.

The climate of this continent appears not to be disagreeable, notwithstanding the violent complaints which some have made about it. The heat has never been excessive in summer; nor is the cold intolerable in winter. Storms of thunder and lightning are frequent; but these are common to all warm countries; and it has been supposed (though upon what foundation does not well appear) that were the country cleared of wood, and inhabited, these would in a great measure cease. A shock of an earthquake has likewise been felt; but these natural calamities are incident to some of the finest countries in the world. It is not known whether there are any volcanoes or not.

26
Account of
the inhabi-
tants.

The inhabitants of New Holland are by all accounts represented as the most miserable and savage race of mortals, perhaps, existing on the face of the earth. They go entirely naked; and though pleased at first with some ornaments which were given them, they soon threw them away as useless. It does not appear, however, that they are insensible of the benefits of clothing, or of some of the conveniencies which their new neighbours are in possession of. Some of them, whom the colonists partly clothed, seemed to be pleased with the comfortable warmth they derived from it; and they all express a great desire for the iron tools which they see their neighbours make use of. Their colour, in the opinion of captain Cook, is rather a deep chocolate than a full black; but the filth with which their skins

are covered, prevents the true colour of them from appearing. At some of their interviews with the colonists, several droll instances happened of their mistaking the negroes among the colonists for their own countrymen. Notwithstanding their disregard for European finery, they are fond of adorning, or rather deforming, their bodies with scars; so that some of them cut the most hideous figure that can be imagined. The scars themselves have an uncommon appearance. Sometimes the flesh is raised several inches from the skin, and appears as if filled with wind; and all these seem to be reckoned marks of honour among them. Some of them perforate the cartilage of the nose and thrust a large bone through it, an hideous kind of ornament humorously called by the sailors their *sprit-sail yard*. Their hair is generally so much clotted with the red gum already mentioned, that they resemble a mop. They also paint themselves with various colours like most other savages: they will also sometimes ornament themselves with beads and shells, but make no use of the beautiful feathers procurable from the birds of the country. Most of the men want one of the fore teeth in the upper jaw; a circumstance mentioned by Dampier and other navigators; and this also appears to be a badge of honour among them. It is very common among the women to cut off the two lower joints of the little finger; which, considering the clumsiness of the amputating instruments they possess, must certainly be a very painful operation. This was at first supposed to be peculiar to the married women, or those who had borne children, but some of the oldest women were found without this distinction, while it was observed in others who were very young.

The New Hollanders appear extremely deficient in the useful arts. Of the cultivation of the ground they have no notion; nor can they even be prevailed upon to eat bread or dressed meat. Hence they depend entirely for subsistence on the fruits and roots they can gather, with the fish they catch. Governor Phillip also mentions their frequent setting fire to the grass, in order to drive out the opossums and other animals from their retreats; and we have already taken notice of their using decoys for quails. As all these resources, however, must be at best precarious, it is no wonder that they are frequently distressed for provisions. Thus, in the summer-time they would eat neither the shark nor sting-ray; but in winter any thing was acceptable. A young whale being driven ashore, was quickly cut in pieces and carried off. They broiled it only long enough to scorch the outside; and in this raw state they eat all their fish. They broil also the fern root and another whose species is unknown. Among the fruits used by them is a kind of wild fig; and they eat also the kernels of a fruit resembling the pine-apple. The principal part of their subsistence, however, is fish; and when these happened to be scarce, they were wont to watch the opportunity when the colonists hauled the seine, and often seized the whole, though a part had formerly been offered or given them. They sometimes strike the fish from the canoes with their spears, sometimes catch them with hooks, and also make use of nets, contrary to the assertion of Dr Hawkesworth, who says that none of these are to be met with among them. Their nets are generally made of the fibres of the flax plant, with very little preparation, and are strong.

New Hol-
land.

strong and heavy; the lines of which they are composed twisted like whip-cord. Some of them, however, appear to be made of the fur of an animal, and others of cotton. The meshes of their nets are made of very large loops artificially inserted into each other, but without any knots. Their hooks are made of the inside of a shell very much resembling mother-of-pearl. The canoes in which they fish are nothing more than large pieces of bark tied up at both ends with vines; and considering the slight texture of these vessels, we cannot but admire the dexterity with which they are managed, and the boldness with which they venture in them out to sea. They generally carry fire along with them in these canoes, to dress their fish when caught. When fishing with the hook, if the fish appears too strong to be drawn ashore by the line, the canoe is paddled to the shore; and while one man gently draws the fish along, another stands ready to strike it with a spear, in which he generally succeeds. There is no good reason for supposing them to be cannibals, and they never eat animal substances but raw or next to it. Some of their vegetables are poisonous when raw, but deprived of this property when boiled. A convict unhappily experienced this by eating them in an unprepared state; in consequence of which he died in 24 hours. The dislike of the New Hollanders to the European provisions has already been mentioned: if bread be given them, they chew and spit it out again, seldom choosing to swallow it. They like salt beef and pork rather better; but they could never be brought to taste spirits a second time.

The huts of these savages are formed in the most rude and barbarous manner that can be imagined. They consist only of pieces of bark laid together in the form of an oven, open at one end, and very low, though long enough for a man to lie at full length. There is reason, however, to believe, that they depend less on them for shelter than on the caverns with which the rocks abound. They go invariably naked, as has already been observed; though we must not imagine that the custom of going naked inures them so to the climate as to make them insensible to the injuries of the weather. The colonists had repeated opportunities of observing this, by seeing them shivering with cold in the winter time, or huddling together in heaps in their huts or in caverns, till a fire could be kindled to warm them. It is probable, however, notwithstanding their extreme barbarity, that some knowledge of the arts will soon be introduced among them, as some have been seen attentively considering the utensils and conveniences of the Europeans, with a view, seemingly, of making similar improvements of their own. It has also been observed, that in some things they possess a very great power of imitation. They can imitate the songs and language of the Europeans almost instantaneously, much better than the latter can imitate theirs by long practice. Their talent for imitation is also discernible in their sculptures representing men and other animals every where met with on the rocks; which, though rude, are very surprising for people who have not the knowledge even of constructing habitations in the least comfortable for themselves, or even clothes to preserve them from the cold.

In their persons, the New Hollanders are active, vi-

gorous, and stout, though generally lean. Dampier asserts that they have a dimness of sight; though later navigators have determined this to be a mistake, ascribing to them, on the contrary, a quick and piercing sight. Their sense of smelling is also very acute. One of them having touched a piece of pork, held out his finger for his companion to smell with strong marks of disgust. The only kind of food they eagerly accept of is fish. Their behaviour with regard to the women has been hitherto unaccountable to the colonists. Few of them, comparatively speaking, have been seen; and these have sometimes kept back with the most jealous sensibility; sometimes offered with the greatest familiarity. Such of the females as have been seen, have soft and pleasing voices; and notwithstanding their barbarism and excessive rudeness, seem not to be entirely destitute of modesty.

The New Hollanders generally display great personal bravery on the appearance of any danger. An old man, whom governor Phillip had treated with some familiarity, took occasion to steal a spade; but being taken in the fact, the governor gave him a few slight slaps on the shoulder; on which the old man caught hold of a spear, and, coming up to him, seemed for some time determined to strike, though had he done so it would have been impossible for him to escape, being then surrounded by the officers and soldiers. No encounters between parties of the natives themselves have been observed, though from some circumstances it appears that wars are carried on among them. They have more than once been seen assembled as if bent on some expedition. An officer one day met 14 of them marching along in a regular Indian file through the woods, each man having a spear in one hand and a stone in the other. A chief appeared at their head, who was distinguished from the rest by being painted. They passed on peaceably, though greatly superior in number to our people. On another occasion they offered no hostilities when assembled to the number of 200 or 300, and meeting the governor attended only by a small party. With all their courage, however, they are much afraid of a musket, and almost equally so of a red coat, which they know to be the martial dress of the Europeans. The mischief which they have hitherto done has been exercised only on some straggling convicts, most of whom probably have been the first aggressors.

Though these savages allow their beards to grow to a considerable length, it does not appear that they look upon them to be any ornament, but rather the contrary, as appears from the following instance. Some young gentlemen belonging to the *Sirius*, one day met an old man in the woods with a beard of considerable length. This his new acquaintance let him know that they would rid him of, stroking their chins, and showing him the smoothness of them at the same time. At length the old fellow consented; and one of the youngsters taking a penknife from his pocket, and making the best substitute for lather he could, performed the operation with such success that the Indian seemed highly delighted. In a few days he paddled alongside of the *Sirius* again, pointing to his beard; but could not by any means be prevailed upon to enter the ship. On this a barber was sent down to him, who again freed him from his beard, at which

New Hol-
land.

New Hol-
land.

which he expressed the utmost satisfaction. It has, however, been found impossible to form any kind of permanent intercourse with the natives, though many attempts have been made for that purpose; but in his letter above quoted, governor Phillip declares that he has not the least apprehension of their doing any damage to the colony. At first the colonists imagined the spears of the New Hollanders to be very trivial weapons; but it now appears that they are capable of inflicting very grievous and mortal wounds. They are sometimes pointed with a sharp piece of the same reed of which the shafts are made, but more frequently with the sharp bone of the sting-ray. They certainly burn their dead; which perhaps has given rise to the report of their being cannibals. Governor Phillip, observing the ground to be raised in several places, caused one of these tumuli to be opened, in which were found a jaw-bone half consumed and some ashes. From the manner in which the ashes are deposited, it appears that the body has been laid at length, raised from the ground a little space, and consumed in that posture; being afterwards lightly covered with mould.

The only domestic animals they have are the dogs already mentioned, which resemble the fox-dog of England. In their language these animals are called *dingo*; but all other quadrupeds without exception they name *kangaroo*.—They seem very little given to thieving in comparison with the inhabitants of most of the South Sea islands; and are very honest among themselves, leaving their spears and other implements open on the beach, in full and perfect security of their remaining untouched. They are very expert at throwing their javelins, and will hit a mark with great certainty at a considerable distance; and it seems that sometimes they kill the kangaroo with this weapon, as a long splinter of one of the spears was taken out of the thigh of one of these animals, the flesh having closed over it completely. The people are more numerous than was at first imagined, though still the number of inhabitants must be accounted few in comparison to the extent of country; and there is great reason to believe that the interior parts are uninhabited.

The New Hollanders bake their provisions by the help of hot stones, like the inhabitants of the South-sea islands. They produce fire with great facility according to Captain Cook, but with difficulty according to later accounts, and spread it in a wonderful manner. To produce it, they take two pieces of dry soft wood; one is a stick about eight or nine inches long, the other piece is flat. The stick they shape into an obtuse point at one end; and pressing it upon the other, turn it nimbly, by holding it between both their hands, as we do a chocolate-mill; often shifting their hands up, and then moving them down upon it, to increase the pressure as much as possible. By this method they get fire in less than two minutes, and from the smallest spark they increase it with great speed and dexterity. “We have often seen (says captain Cook) one of them run along the shore, to all appearance with nothing in his hand, who stooping down for a moment, at the distance of every fifty or an hundred yards left fire behind him, as we could see, first by the smoke, and then by the flame along the drift of wood and other litter which was scattered along the place. We had the curiosity to examine

one of these planters of fire when he set off, and we saw him wrap up a small spark in dry grass, which when he had run a little way, having been fanned by the air that his motion produced, began to blaze; he then laid it down in a place convenient for his purpose, inclosing a spark of it in another quantity of grass, and so continued his course.”

HOLLAND in commerce, a fine and close kind of linen, so called from its being first manufactured in Holland.

HOLLAR (Wenceslaus), a celebrated engraver, born at Prague in 1607. His parents were in a genteel line of life; and he was at first designed for the study of the law. But the civil commotions, which happened in his youth, ruining his family affairs, he was obliged to shift for himself; and by discovering some genius for the arts, he was placed with Marian, a very able designer and engraver of views. Being himself a man of great ingenuity, he profited hastily from the instruction of his tutor. He principally excelled in drawing geometrical and perspective views and plans of buildings, ancient and modern cities and towns; also landscapes, and every kind of natural and artificial curiosities; which he executed with a pen in a very peculiar style, excellently well adapted to the purpose. He travelled through several of the great cities of Germany; and, notwithstanding all his merit, met with so little encouragement, that he found it very difficult to support himself. The earl of Arundel being in Germany took him under his protection, brought him to England, and recommended him to the favour of Charles I. He engraved a variety of plates from the Arundel collection, and the portrait of the earl himself on horseback. The civil wars, which happened soon after in England, ruined his fortune. He was taken prisoner, with some of the royal party, and with difficulty escaped; when he returned to Antwerp, and joined his old patron the earl of Arundel. He settled in that city for a time, and published a considerable number of plates; but his patron going to Italy soon after for the benefit of his health, Hollar fell again into distress, and was obliged to work for the print and book-sellers of Antwerp at very low prices. At the restoration he returned into England; where, though he had sufficient employment, the prices he received for his engravings were so greatly inadequate to the labour necessarily required, that he could but barely subsist; and the plague, with the succeeding fire of London, putting for some time an effectual stop to business, his affairs were so much embarrassed, that he was never afterwards able to improve his fortune. It is said that he used to work for the booksellers at the rate of four-pence an hour; and always had an hour glass before him. He was so very scrupulously exact, that when obliged to attend the calls of nature, or whilst talking, though with the persons for whom he was working and about their own business, he constantly laid down the glass, to prevent the sand from running. Nevertheless, all his great industry, of which his numerous works bear sufficient testimony, could not procure him a sufficient maintenance. It is melancholy to add, that on the verge of his 70th year, he was attached with an execution at his lodgings in Gardener's lane, Westminster; when he desired only the liberty of dying in his bed, and that he might not be removed to any other prison than

Holland,
Hollar.

Hollar
Holocaust.

the grave: a favour which it is uncertain whether he obtained or not. He died, however, in 1677.—His works amount nearly to 24,000 prints, according to Vertue's Catalogue; and the lovers of art are always zealous to collect them. Generally speaking, they are etchings performed almost entirely with the point; and their merits are thus characterised by Mr Strutt: "They possess great spirit, with astonishing freedom and lightness, especially when we consider how highly he has finished some of them. His views of abbeys, churches, ruins, &c. with his shells, muffs, and every species of still life, are admirable; his landscapes frequently have great merit; and his distant views of towns and cities are not only executed in a very accurate, but a very pleasing manner." A somewhat colder character is given of them by Mr Gilpin in his Essay on Prints: "Hollar gives us views of particular places, which he copies with great truth, unornamented as he found them. If we are satisfied with exact representations, we have them no where better than in Hollar's works: but if we expect pictures, we must seek them elsewhere. Hollar was an antiquarian and a draughtsman; but seems to have been little acquainted with the principles of painting. Stiffness is his characteristic, and a painful exactness void of taste. His larger views are mere plans. In some of his smaller, at the expence of infinite pains, something of an effect is sometimes produced. But in general, we consider him as a repository of curiosities, a record of antiquated dresses, abolished ceremonies, and edifices now in ruins."

HOLLOA, in the sea-language, an exclamation of answer, to any person who calls to another to ask some question, or to give a particular order. Thus, if the master intends to give any order to the people in the main-top, he previously calls, *Main-top, hoay!* to which they answer, *Holloa!* to show that they hear him, and are ready. It is also the first answer in hailing a ship at a distance. See **HAILING**.

HOLLY, in botany. See **ILEX**.

Sea-HOLLY. See **ERYNGIUM**.

HOLM (Sax. *bulmus, insula amnica*), denotes an isle or fenny ground, according to Bede; or a river-island. And where any place is called by that name, and this syllable is joined with any other in the names of places, it signifies a place surrounded with water; as the Flatholmes and Stepholmes in the Severn near Bristol: but if the situation of the place is not near the water, it may then signify a hilly place; *holm* in Saxon, signifying also "a hill or cliff."

HOLOCAUST (formed from *ολος* "whole," and *καίω* "I consume with fire"), a kind of sacrifice, wherein the whole offering is burnt or consumed by fire, as an acknowledgement that God, the creator, preserver, and lord of all, was worthy of all honour and worship, and as a token of men giving themselves entirely up to him. It is called also in Scripture a *burnt-offering*.—Sacrifices of this sort are often mentioned by the heathens as well as Jews; particularly by Xenophon, *Cyropæd. lib. viii. p. 464. ed. Hutchins.* 1738, who speaks of sacrificing holocausts of oxen to Jupiter, and of horses to the sun: and they appear to have been in use long before the institution of the other Jewish sacrifices by the law of Moses; (see Job i. 5. xlii. 8. and Gen. xxii. 13. viii. 20). On this account,
N^o 156.

the Jews, who would not allow the Gentiles to offer on their altar any other sacrifices peculiarly enjoined by the law of Moses, admitted them by the Jewish priests to offer holocausts; because these were a sort of sacrifices prior to the law, and common to all nations. During their subjection to the Romans, it was no uncommon thing for those Gentiles to offer sacrifices to the God of Israel at Jerusalem. Holocausts were deemed by the Jews the most excellent of all their sacrifices. It is said, that this kind of sacrifice was in common use among the heathens, till Prometheus introduced the custom of burning only a part, and reserving the remainder for his own use. See **SACRIFICE**.

HOLOFERNES, lieutenant general of the armies of Nebuchadonosor king of Assyria, who having in a remarkable encounter overcome Arphaxad king of the Medes, sent to all the neighbouring nations with an intention of obliging them this way to submit to his empire, pretending that there could be no power capable of resisting him. At the same time Holofernes, at the head of a powerful army, passed the Euphrates, entered Cilicia and Syria, and subdued almost all the people of these provinces.

Being resolved to make a conquest of Egypt, he advanced towards Judæa, little expecting to meet with any resistance from the Jews. In the mean time, he was informed that they were preparing to oppose him; and Achior the commander of the Ammonites, who had already submitted to Holofernes, and was with some auxiliary troops in his army, represented to him that the Hebrews were a people protected in a particular manner by God Almighty so long as they were obedient to him; and therefore he should not flatter himself with expectations of overcoming them, unless they had committed some offence against God, whereby they might become unworthy of his protection. Holofernes, disregarding this discourse, commanded Achior to be conveyed within sight of the walls of Bethulia, and tied to a tree, and left there, whither the Jews came and loosed him.

In the mean time Holofernes formed the siege of Bethulia; and having cut off the water which supplied the city, and set guards at the only fountain which the besieged had near the walls, the inhabitants were soon reduced to extremity, and resolved to surrender, if God did not send them succours in five days. Judith, being informed of their resolution, conceived the design of killing Holofernes in his camp. She took her finest clothes, and went out of Bethulia with her maid-servant; and being brought to the general, she pretended that she could no longer endure the sins and excesses of the Jews, and that God had inspired her with the design of surrendering herself to him.—As soon as Holofernes saw her, he was taken with her beauty; and some days after invited her to a great feast, which he prepared for the principal officers of his army. But he drank so much wine, that sleep and drunkenness hindered him from satisfying his passion. Judith, who in the night was left alone in his tent, cut off his head with his own sword; and departing with her servant, from the camp, she returned to Bethulia with the head of Holofernes. As soon as it was day, the besieged made a sally upon the enemies, who going into their general's tent, found his headless carcase wallowing in its own blood. They then

Hologra-
phum
||
Holothu-
ria.

then discerned that Judith had deceived them, and fled with precipitation, leaving the camp abounding with rich spoils: the Jews pursued them, killed a great number of them, and returned loaded with booty.

There is a great diversity of opinions concerning the time when this war between Holofernes and the Jews happened. Some date it from the captivity of Babylon, in the reign of Manasseh, and pontificate of Eliakim the high-priest; others place it at some time after the captivity; and some doubt the truth of the whole transaction. See the article JUDITH.

HOLOGRAPHUM (composed of *ολος* "all," and *γραφω* "I write"), in the civil law, something written wholly in the hand-writing of the person who signs it. The word is chiefly used in speaking of a testament written wholly in the testator's own hand.

The Romans did not approve of holographic testaments; and, though Valentinian authorised them by a novel, they are not used where the civil law is in full force.

HOLOSTEUM, in botany; A genus of the tri-gynia order, belonging the triandria class of plants; and in the natural method ranking under the 22d order, *Caryophyllei*. The calyx is pentaphyllous; the petals five, the capsule unilocular, and nearly cylindrical, opening at top.

HOLOTHURIA, in zoology, a genus belonging to the order of vermes mollusca. The body detached, naked, gibbous, terminated by the anus. Many tentacula at the other extremity, surrounding the mouth. There are nine species, all inhabitants of the ocean. The following descriptions of three species are given by Mr Barbut.

1. The tremula, or quivering holothuria, "commonly measures eight inches in length when dead; but alive it extends itself to more than a foot, or contracts its body into a ball. Its figure is cylindric, the diameter of which is every way equal to an inch and a few lines. The back of a dark brown proudly bears a variety of fleshy pyramid-like nipples, of a dark colour likewise at their basis, but white at their apex. They are observed to be of two different sizes; the larger occupy the length of the back, in number 14 on each side, at the distance of six lines one from the other, when the holothuria is contracted, but the intervening space is full eight lines when the animal is extended. Others like these are placed here and there promiscuously. The less are scattered in like manner, without order, in every part of the back. Out of them all exudes a whitish mucilage serving to lubricate the body. Hence all the foresaid nipples seem to be so many glands furnished with an excretory duct, the aperture of which is so minute as not to be discoverable by the help of a common glass. That they are moreover provided with various muscles follows hence, that the holothuria can raise and obliterate them at pleasure. While the larger papillæ are quite erect, their axis and the diameter of their base measures three lines. The belly or part opposite to the back in the holothuria is of a pale brown and set all over with cylindric tentacula, in such numbers that the head of a pin could scarce find room between. Their diameter is not much above a line, and their length is that of four lines. They are of a shining whiteness, except the extremity which is of a dark colour,

VOL. VIII. Part II.

and shaped like a socket. By the help of these tentacula the holothuria fixes its body at the bottom of the sea, so as not to be easily forced away by tempests, which would otherwise happen the more frequently, as this zoophite dwells near the shores where the water scarce rises to a fathom's height. Now if it adheres to other bodies by means of its ventral tentacula, their point must necessarily have the form of a socket, as the cuttle-fish, sea-urchins, and star-fish have theirs shaped, by which they lay hold of any other body. From this situation of the holothuria at the bottom of the sea, which it also retains when kept in a vessel filled with sea-water, it must be evident to any one, that I have not groundlessly determined which was its back, and which its belly, which otherwise in a cylindric body would have been a difficult task. But as all animals uniformly walk or rest upon their bellies, and the holothuria has likewise that part of its body turned to the earth on which the cylindric tentacula are to be seen, it is clear that part is the abdomen or belly of this zoophite. However, both the abdominal and dorsal tentacula are raised and obliterated at the animal's pleasure; from which it is no light conjecture to conclude, that they are furnished with elevating and depressing muscles, and particularly because all the foresaid tentacula disappear after the animal's death: and hence it farther appears, that all naturalists have given the representation of a dead holothuria, seeing they have assigned it no tentacula. I entertain some doubt whether the illustrious Linnæus himself did not draw his generical character of the holothuria from a dead subject, as he makes no mention of these tentacula."

2. The physalis, or bladder-shaped holothuria. The body of this species is oval, approaching to triangular, of a glossy transparency; the back sharp edged, of a dark green colour, whence run out a number of sinews: anteriorly the body is of a reddish hue. The trunk spiral, reddish towards the thicker end. Many tentacula of unequal length under that thicker end; the shorter ones are taper and thicker, the middle ones capillary, the point clay colour and in shape like a ball; the rest which are longer are filiform, of which the middlemost is thicker and twice as long. Brown, in his Jamaica, calls it a diaphanous bladder with numerous tentacula representing a man's belly; above it is furnished with a comb full of cells; under the other extremity hang a number of branchy tentacula. It inhabits the seas.

3. The Pentactes, or five-rowed holothuria, has the mouth encompassed with tentacula, the body bearing tentacula five different ways. The animal is of a red colour, nearly oval, or somewhat cylindrical, assuming various shapes. The mouth is set round with ten rays bristly at the points. The body longitudinally dotted in five places with clay-coloured hollow warts, situate two together. It inhabits the sea of Norway, taking in and casting out again the water, as it either swims or dives to the bottom.

HOLSTEIN, a duchy of Germany, bounded by the German ocean on the west; the Baltic, or the gulph of Lubeck, on the east; the duchy of Mecklenburg on the south-east; that of Bremen, with the river Elbe, on the south-west; and Lauenburg, with the territory of Hamburg, on the south. Its greatest

length

Holothu-
ria,
Holstein.

Plate
CCXXXV.

Holstein length is about 80 miles, and its breadth 60. The diocese of Eutin, and the county of Ranzau, though they make a part of the duchy of Holstein, yet being lands belonging to the empire and circle, shall be described separately.

A great part of this country consists of rich marsh-land, which being much exposed to inundations both from the sea and rivers, dykes have been raised at a great expence to guard and defend them. The pastures in the marshes are so rich, that cattle are bred in vast numbers and fattened in them, and great quantities of excellent butter and cheese made of their milk. They are also very fruitful in wheat, barley, pease, beans, and rape-feed. In the more barren, sandy, and heathy parts of the country, large flocks of sheep are bred and fed: nor are orchards wanting, or woods, especially of oak and beech; nor turf, poultry, game, and wild-fowl. Here is a variety both of sea and river fish; and the beef, veal, mutton, and lamb, are very fat and palatable. Holstein is also noted for beautiful horses. The gentry usually farm the cows upon their estates to a Hollander, as he is called, who for every cow pays from six to ten rix-dollars; the owner providing pasture for them in summer, and straw and hay in winter. It is no uncommon thing here to drain the ponds and lakes once in three or four years, and sell the carp, lampreys, pikes, and perch, found in them; then sow them for several years after with oats, or use them for pasture; and after that lay them under water again, and breed fish in them. There are hardly any hills in the country; but several rivers, of which the principal are the Eyder, the Stor, and the Trave. The duchy contains about 30 towns great and small: most part of the peasants are under villenage, being obliged to work daily for their lords, and not even at liberty to quit their estates. The nobility and the proprietors of manors are possessed of the civil and criminal jurisdiction, with other privileges and exemptions. Formerly there were diets, but now they seem to be entirely laid aside: meetings, however, of the nobility are still held at Kiel. The predominant religion here is Lutheranism, with superintendencies as in other Lutheran countries. In several places the Jews are allowed the exercise of their religion. At Gluckstadt and Altena are both Calvinist and Popish churches; and at Kiel a Greek Russian chapel. Besides the Latin schools in the towns, at Altena is a gymnasium, and at Kiel an university. Notwithstanding this country's advantageous situation for commerce, there are few manufactures and little trade in it. Hamburg and Lubec supply the inhabitants with what they want from abroad; from whence and Altena they export some grain, malt, groats, starch, buck-wheat, pease, beans, rapefeed, butter, cheese, sheep, swine, horned cattle, horses, and fish. The manufactures of the duchy are chiefly carried on at Altena, Kiel, and Gluckstadt. The duchy of Holstein consists of the ancient provinces of Holstein, Stormar, Ditmarsh, and Wagria. It belongs partly to the king of Denmark and partly to the dukes of Holstein Gottorf and Ploen. Anciently the counts of Holstein were vassals of the dukes of Saxony; but afterwards they received the investiture of their territories from the emperor, or the bishops of Lubec in the emperor's name, though now

the investiture is given by the emperor in person. The king of Denmark appoints a regency over his part of Holstein and the duchy of Sleswick, which has its office at Gluckstadt. The seat of the great duke's privy council and regency-court, together with the chief consistory, which is united to it, is at Kiel: there are many inferior courts and consistories, from which an appeal lies to the higher. In the duchy of Holstein, the government of the convents and nobility is alternately in the king and duke for a year, from Michaelmas to Michaelmas. The person in whom the government is lodged administers it by his regency. In some cases an appeal lies from this court to the Aulic council or chamber at Wetzlar: the convents, the nobility, and the proprietors of manors in the country, have a civil and criminal jurisdiction over their estates. The revenues of the sovereigns arise principally from their demesnes and regalia; besides which, there is a land and several other taxes and imposts. The duke's income, setting aside his ducal patrimony, has been estimated at 70,000 or 80,000 pounds. The king usually keeps here some regiments of foot and one of horse. With respect to the duke's military force, it amounts to about 800 men. The king, on account of his share in this country, styles himself *duke of Holstein, Stormar, and Ditmarsh*. The dukes both of the royal and princely house style themselves *heirs of Norway, dukes of Sleswick, Holstein, Stormar, and Ditmarsh*, and counts of Oldenburg and Delmenhorst. On account of Holstein, both the king of Denmark and the grand duke have a seat and voice in the college of the princes of the empire, and in that of the circle. Together with Mecklenburg they also nominate an assessor for this circle in the Aulic chamber. The matricular assessment of the whole duchy is 40 horse and 80 foot, or 800 florins; to the chamber of Wetzlar both princes pay 189 rix-dollars, 31 kruitzers. In 1735, duke Charles Frederic of Holstein Gottorf founded an order of knighthood here, viz. that of St Anne, the ensign of which is a red cross, enamelled, and worn pendant at a red ribbon edged with yellow.—The principal places of that part of the duchy belonging to the king of Denmark and the duke of Ploen are Gluckstadt, Itzhoe, Rendsburg, and Ploen; and that part belonging to the great duke are Kiel, Oldenburg, Preetz, and Altena.

HOLSTENIUS (Lucas), an ingenious and learned German, born at Hamburg in 1596, was bred a Lutheran; but being converted to popery by father Sirmond the Jesuit, he went to Rome, and attached himself to cardinal Francis Barberini, who took him under his protection. He was honoured by three popes; Urban VIII. gave him a canonry of St Peter's; Innocent X. made him librarian of the Vatican; and Alexander VII. sent him in 1655 to queen Christina of Sweden, whose formal profession of the Catholic faith he received at Inspruck. He spent his life in study, and was very learned both in sacred and profane antiquity. He died in 1661; and though he was not the author of any great works, his notes and dissertations on the works of others have been highly esteemed for the judgment and precision with which they are drawn up.

HOLT (Sir John), knight, eldest son of Sir Thomas Holt, serjeant at law, was born in 1642. He entered

Holstein
Holt.

Holt
||
Holyhead.

tered himself of Gray's Inn in 1658; and applied to the common law with so much industry, that he soon became a very eminent barrister. In the reign of James II. he was made recorder of London, which office he discharged with much applause for about a year and a half; but lost his place for refusing to expound the law suitably to the king's designs. On the arrival of the prince of Orange, he was chosen a member of the convention parliament, which afforded him a good opportunity of displaying his abilities; so that, as soon as the government was settled, he was made lord chief justice of the court of king's bench, and a privy counsellor. He continued chief justice for 22 years, with great repute for steadiness, integrity, and thorough knowledge in his profession. Upon great occasions he asserted the law with intrepidity, though he thereby ventured to incur by turns the indignation of both the houses of parliament. He published some reports, and died in 1709.

HOLT (Sax.) "a wood;" wherefore the names of towns beginning or ending with *holt*, as *Buck-holt*, &c. denote that formerly there was great plenty of wood in those places.

HOLY. See HOLINESS.

HOLY-GHOST, one of the persons of the holy Trinity. See TRINITY.

Order of the HOLY GHOST, the principal military order in France, instituted by Henry III. in 1569. It consists of 100 knights, who are to make proof of their nobility for three descents. The king is the grand-master or sovereign; and as such takes an oath on his coronation-day to maintain the dignity of the order.

The knights wear a golden cross, hung about their necks by a blue silk ribbon or collar. But before they receive the order of the Holy-Ghost, that of St Michael is conferred as a necessary degree; and for this reason their arms are surrounded with a double collar.

HOLYHEAD, a town and cape of the isle of Anglesea in Wales, and in the Irish channel, where people usually embark for Dublin, there being three packet-boats that sail for that city every Monday, Wednesday, and Friday, wind and weather permitting. It is 276 miles from London, and has a very convenient harbour for the northern trade, when taken short by contrary winds. It is situated near the extremity of the Isle, and is joined to the north-west part of it by a stone bridge of one arch. It has a small market on Saturdays. The parish is about five or six miles long, and two or three broad, bounded nearly by the sea. The church stands above the harbour, within an old quadrangular fortification, with a bastion at each corner built about 450. On a mountain near it is another old fortification called *Turris Munimentum*, which is an old stone wall without mortar, and in its centre is a small turret, and contains a well of water. Holyhead was frequently formerly visited by Irish rovers, and was defended as a place of consequence. There are several remains of old fortifications and Druidical antiquities in its neighbourhood, as well as chapels of religious worship. The parish church of Holyhead was built in the reign of Edward III. and is in the form of a cross, with a porch and steeple very antique. There was an old chapel near the church, now converted into a school-house. A salt-house was

erected on an island in the harbour in queen Anne's reign, but it is now in ruins. The town is little more than a fishing town, rendered considerable by being the place of passage to Ireland. It has three good inns. The passage hence to Ireland is in general about twelve hours. There is no fresh water here except from rain, nor any bread sold but what comes from Ireland. A bath and assembly-room were erected here in 1770. Under the mountains that overhang the town is a large cavern in the rock, supported by natural pillars, called the Parliament-house, accessible only by boats, and the tide runs into it. If this harbour was properly repaired, and ware-houses built, it would be very convenient for the Irish to import such of their goods as pay English duty, it being but a few hours sail from Dublin. Besides, the Dublin merchants might come over with the packets to see their goods landed. The commodities are, butter, cheese, bacon, wild-fowl, lobsters, crabs, oysters, razor-fish, shrimps, herrings, cod-fish, whittings, whiting-pollacks, cole-fish, sea-tench, turbot, soles, flounders, rays, and plenty of other fish. On the rocks the herb grows of which they make kelp, a fixed salt used in making glass, and in alum works. In the neighbourhood there is a large vein of white fullers earth and another of yellow, which might be useful to fullers. On the isle of Skerries, nine miles to the north, is a light-house, which may be seen 24 miles off. Large flocks of puffins are often seen here; they all come in one night, and depart in the same manner.

HOLY-ISLAND, a small island lying on the coast of England, 10 miles south-east of Berwick, in Northumberland. Bede calls it a *semi-island*, being, as he observes, twice an island and twice continent in one day: for at the flowing of the tide, it is encompassed by water; and at the ebb, there is an almost dry passage, both for horses and carriages, to and from the main land; from which, if measured on a straight line, it is distant about two miles eastward; but on account of some quicksands passengers are obliged to make so many detours, that the length of way is nearly doubled. The water over these flats at spring-tides is only seven feet deep.—This island was by the Britons called *Inis Medicante*; also *Lindisfarne*, from the small rivulet of Lindi or Landi, which here runs into the sea, and the Celtic word *fabren* or "recess;" and on account of its being the habitation of some of the first monks in this country, it afterwards obtained its present name of *Holy-island*. It measures from east to west about two miles and a quarter, and its breadth from north to south is scarcely a mile and a half. At the north-west part there runs out a spit of land of about a mile in length. The monastery is situated at the southermost extremity; and at a small distance north of it stands the village. On this island there is plenty of fish and fowl; but the air and soil are bad. There is not a tree on the island. The village, which stands on a rising ground, consists but of a few scattered houses, chiefly inhabited by fishermen; and it has two inns. The north and east coasts are formed of perpendicular rocks, the other sides sink by gradual slopes to the sands. There is a commodious harbour, defended by a block-house; which last was surprised and taken in 1715, but was soon invested and retaken.

Holy-island, though really part of Northumberland, belongs to Durham; and all civil disputes must be de-

Holyhead,

Island.

Holy-
Island.

terminated by the justices of that county.—It was a very ancient episcopal seat. Ardan the first bishop, after presiding in it 14 years, died and was buried here A. D. 651. Finan, his successor, built a wooden church, thatched with reeds, but before the end of the century covered with lead by bishop Eadbert. St Cuthbert, who from a poor shepherd became monk of Melrose 15 years, was prior here 12 more, when he retired to one of the barren Farn rocks, from whence he was called to this see, which he held only two years, and returned to his retirement, where he died, and was buried at the east end of his oratory, where his stone coffin is still shown. His body was found fresh 11 years after his death. Lindisfarn was ruined by the Danes, A. D. 793, when the monks carried his body about for seven years, and at last settled at Chester-le-street, whither the see was translated, and where it continued many years. On a second destruction of the monastery by the Danes they were removing to Rippon, but stopped by a miracle at Durham, where the saint continued till the reformation, when his body was found entire, and privately buried in a wooden coffin, as some pretend, near the clock, but more probably in the ground under where his shrine stood. The entrochi found among the rocks at Landisfarn are called St Cuthbert's beads, and pretended to be made by him in the night. Eighteen bishops sat here

6

till the removal of the see to Chester, which had eight more till the removal to Durham, A. D. 995. Lindisfarn became a cell to that Benedictine monastery, valued at 48 l. *per ann.* The north and south walls of the church are standing, much inclined; part of the west end remains, but the east is down. The columns of the nave are of four different sorts, 12 feet high and 5 feet diameter, massy and richer than those of Durham; the bases and capitals plain, supporting circular arches. Over each arch are large windows in pairs, separated by a short column, and over these are smaller single windows. In the north and south walls are some pointed arches. The length of the body is 138 feet, breadth 18 feet, and with the two aisles 36 feet; but it may be doubted whether there ever was a transept. One arch of the centre tower remains adorned as is its entrance from the nave with Saxon zigzag. Somewhat to the east is the base of a cross, and to the west the present parish-church (A).

Holy-Rood Day, a festival observed by the Roman catholics, in memory of the exaltation of our Saviour's cross. See CROSS and EXALTATION.

HOLYWELL, a town of North Wales, in the county of Flint. It is a place of great note, for the well of St Winnifred, who is reputed a virgin martyr; and it is much frequented by people that come to bathe in it, as well as by popish pilgrims out of devotion. The spring

(A) A reference was inadvertently made to this article for a description of BAMBOROUGH, as if it had been situated upon, or belonged to, *Holy-Island*.—BAMBOROUGH lies several miles to the south, and is situated on the main land. The town is now an inconsiderable village; but it once was a royal borough, and sent two members: it even gave name to a large tract extending southward, which was called *Bamboroughshire*. It had also three religious foundations; a house of friars preachers founded by Henry III. a cell of canons regular of St Austin, and an hospital. Its very ancient castle stands on an almost perpendicular rock close to the sea, and accessible only on the south-east side, on a spot where, according to the monkish historians, there stood the castle or palace of the kings of Northumberland; built, as it is said, by king Ida, who began his reign about the year 559. Part of the present ruins are by some supposed to be the remains of king Ida's work. The ancient name of this place was, it is said, *Bebbanborough*; whose name Cambden, from the authority of Bede, imagines borrowed from Bebb, Ida's queen: but the author of the additions to that writer is of a contrary opinion, as in the Saxon copy it is called *Cynelicanberg*, or the "royal mansion." According to Florilegus, king Ida at first fenced it only with a wooden inclosure, but afterwards surrounded it with a wall. It is thus described by Roger Hoveden, who wrote in the year 1192: "Bebba is a very strong city, but not exceeding large; containing not more than two or three acres of ground. It has but one hollow entrance into it, which is admirably raised by steps. On the top of the hill stands a fair church; and in the western point is a well curiously adorned, and of sweet clean water." This castle was besieged anno 642 by Penda, the Pagan king of the Mercians, who, as the story goes, attempted to burn it: for which purpose he laid vast quantities of wood under the walls, and set fire to it as soon as the wind was favourable; but no sooner was it kindled, than by the prayers of St Adian, the wind changed and carried the flames into his camp, so that he was obliged to raise the siege. In 710, king Osred, on the death of Alfred his father, took shelter in this castle with Brithric his tutor or guardian; one Edulph having seized the crown, by whom, with his partizans, they were unsuccessfully besieged. Brithric made so gallant a defence, that the siege was turned into a blockade, which gave the loyal subjects time to arm in defence of their young king. On their marching hither to his relief, Edulph fled, but was followed, taken, and put to death by Brithric, who thereby securely seated Osred on the throne, when this castle became his palace. In the reign of Egbert, Kenulph bishop of Lindisfarn was confined here 30 years from 750 to 780. In 933, it was plundered and totally ruined by the Danes; but being of great importance in defending the northern parts against the continual incursions of the Scots, it was soon after repaired, and made a place of considerable strength. It is said to have been in good repair at the time of the conquest, when it was probably put into the custody of some trusty Norman, and had in all likelihood some additions made to its works; and this is the more probable, as the present area, contained within its walls, measures upwards of 80 acres, instead of three, as when described by Hoveden. About the year 1095, it was in the possession of Robert de Mowbray earl of Northumberland, who engaging in some treasonable practices against William Rufus, that king laid siege to it, and obliged it to surrender. In the next reign it was entrusted by Henry I. to Eustace Fitz John, who was dispossessed of it and his other employments by king Stephen

Holyoak, spring gushes forth with such impetuosity, that at a small distance it turns several mills. Over the spring is a chapel built upon pillars, and on the windows are painted the history of St Winnifred's life. There is a moss about the well, which some foolishly imagine to be St Winnifred's hair. W. Long. 3. 15. N. Lat. 54. 23.

HOLYOAK (Francis), author of the Latin dictionary, became rector of South-ham in Warwickshire in 1604; and being greatly esteemed, was chosen member of the convocation in the first year of Charles I.'s reign. He suffered much for the king; and died in 1653, aged 87. His son Thomas made enlargements to the said Dictionary.

HOLYWOOD (John), or **HALIFAX**, or *Sacro-bosco*, was, according to Leland, Bale, and Pitts, born at Halifax in Yorkshire; according to Stainhurst, at Holywood near Dublin; and, according to Dempster and Mackenzie, in Nithsdale in Scotland. The last-mentioned author informs us, that, having finished his studies, he entered into orders, and was made a canon regular of the order of St Augustin in the famous monastery of Holywood in Nithsdale. The English biographers, on the contrary, tell us, that he was educated at Oxford. They all agree, however, in assert-

ing that he spent most of his life at Paris; where, says Mackenzie, he was admitted a member of the university on the fifth of June in the year 1221, under the syndics of the Scotch nation; and soon after elected professor of mathematics, which he taught for many years with applause. We are told by the same author, that he died in 1256, as appears from the inscription on his monument in the cloisters of the convent of St Maturine at Paris. Holywood was certainly the first mathematician of his time. He was cotemporary with Roger Bacon, but probably older by about 20 years. He wrote, 1. *De sphaera mundi*; often reprinted, and illustrated by various commentators. 2. *De anni ratione, seu de computo ecclesiastico*. 3. *De algorismo*, printed with *Comm. Petri Cirvilli Hisp.* Paris 1498.

HOMAGE, in law, is the submission, loyalty, and service, which a tenant promised to his lord when he was first admitted to the land which he held of the lord in fee: also that owing to a king, or to any superior.

HOMBERG (William), a celebrated physician, chemist, and philosopher, was the son of a Saxon gentleman, and born in Batavia, in the East Indies, in 1652. His father afterwards settling at Amsterdam, William there prosecuted his studies; and from thence removed

Homage,
Homberg.

Stephen, that king being jealous of his attachment to Maud, daughter of Henry I. Irritated at this, Fitz John delivered the castle of Alnwick to David king of Scotland, and brought to his aid all the forces he could raise; he was, however, afterwards reconciled to king Stephen, and held the manors of Burg and Knaresborough in Yorkshire, but never recovered the government of this castle.

In the 16th of Henry II. some great repairs seem to have been done here, as in Madox's history of the exchequer, under the article of Amercements, it appears one William, son of Waldef, was fined five marks for refusing his assistance in the king's works at Baenburgh castle. Its keep is supposed to have been the work of this reign.

Edward I. summoned Baliol to meet him here 1296; and on his refusal invaded Scotland, and took him prisoner. Edward II. sheltered Gaveston here 1310. It was taken by the Yorkists after the battle of Hexham. In the reign of Elizabeth Sir John Forster, warden of the marches, was governor of it, and made a knight banneret after the battle of Muffelburgh; and his grandson John obtained a grant of both castle and manor from James I. His descendant Thomas forfeited it in 1715; but his maternal uncle Nathaniel Crew bishop of Durham purchased and bequeathed them to unconfined charitable uses. The ruins are still considerable; but many of them now filled with sand, caught up by the winds which rage here with great violence; and carried to very distant places. The remains of a great hall are very singular; it had been warmed by two fire places of a vast size, and from the top of every window ran a flue like that of a chimney, which reached the summits of the battlements. These flues seem designed as so many supernumerary chimnies to give vent to the smoke that the immense fires of those hospitable times filled the rooms with; for halls smoky, but filled with good cheer, were in those days thought no inconvenience. In the year 1757, the trustees for lord Crew's charity began the repairs of the keep or great tower; the direction and management being committed to Dr Sharp archdeacon of Durham, one of their number; who has made a most judicious and humane application of his lordship's generous bequest. The walls are from 9 to 12 feet thick. The upper parts of the building have been formed into granaries; whence, in times of scarcity, corn is sold to the indigent without any distinction at four shillings per bushel. A hall and some small apartments are reserved by the Doctor, who frequently resides here to see that his noble plan is properly executed.—Among the variety of distressed who find relief from the judicious disposition of this charity, are the mariners navigating this dangerous coast, for whose benefit a constant watch is kept on the top of the tower; from whence signals are given to the fishermen of Holy Island when any ship is discovered in distress, these fishermen by their situation being able to put off their boats when none from the land can get over the breakers. The signals are so regulated as to point out the particular place where the distressed vessel lies. Besides which, in every great storm, two men on horseback patrol the adjacent coast from sun-set to sun-rise, who, in case of any shipwreck, are to give immediate notice at the castle. Premiums are likewise paid for the earliest information of any such misfortune. By these means the lives of many seamen have been, and will be, preserved, who would otherwise have perished for want of timely assistance. Nor does this benevolent arrangement stop here. The shipwrecked mariner finds an hospitable reception in this castle; and is here maintained for a week or longer, as circumstances may require. Here, likewise, are store-houses for depositing the goods which may be saved; instruments and tackle for weighing; and raising the sunken and stranded vessels; and, to complete the whole, at the expence of this fund, the last offices are decently performed to the bodies of such drowned sailors as are cast on shore.

Homberg,
Home.

removed to Jena, and afterwards to Leipzig, where he studied the law. In 1642, he was made advocate at Magdeburg, and there applied himself to the study of experimental philosophy. Some time after he travelled into Italy; and applied himself to the study of medicine, anatomy, and botany, at Padua. He afterwards studied at Bologna; and at Rome learned optics, painting, sculpture, and music. He at length travelled into France, England, and Holland; obtained the degree of doctor of physic at Wittemberg; travelled into Germany and the North; visited the mines of Saxony, Bohemia, Hungary, and Sweden; and returned to France, where he acquired the esteem of the learned. He was on the point of returning into Germany, when M. Colbert being informed of his merit, made him such advantageous offers, as induced him to fix his residence at Paris. M. Homberg, who was already well known for his phosphorus, for a pneumatic machine of his own invention more perfect than that of Guericke, for his microscopes, for his discoveries in chemistry, and for the great number and variety of his curious observations, was received into the academy of sciences in 1691, and had the laboratory of that academy, of which he was one of its principal ornaments. The duke of Orleans, afterwards regent of the kingdom, at length made him his chemist, settled upon him a pension, gave him the most superb laboratory that was ever in the possession of a chemist, and in 1704 made him his first physician. He had abjured the Protestant religion in 1682, and died in 1715. There are a great number of learned and curious pieces of his writing, in the memoirs of the academy of sciences, and in several journals. He had begun to give the elements of chemistry in the memoirs of the academy, and the rest were found among his papers fit for printing.

HOMBERG, a town of Germany, in the circle of the Upper Rhine, and landgraviate of Hesse, seated ten miles north of Francfort, and gives title to one of the branches of the house of Hesse, who is its sovereign. E. Long. 8. 24. N. Lat. 50. 20.

HOMBERG, a town of Germany, in the palatinate of the Rhine, and duchy of Deuxponts. E. Long. 7. 6. N. Lat. 49. 20.

HOME (Henry), Lord Kames, an eminent Scottish lawyer, and author of many celebrated works on various subjects, was descended of a very honourable and ancient family, and born in the year 1696. Lord Kames's grandfather, Henry Home, was a younger son of Sir John Home of Renton, who held the high office of lord justice-clerk, or chief criminal judge of Scotland, in the year 1663. He received the estate of Kames from his uncle George, brother to the then lord justice-clerk. The family of Renton is descended from that of the earls of Home, the representatives of the ancient princes of Northumberland, as appears from the records of the Lion Office.

The county of Berwick in Scotland has the honour of having given birth to this great and useful member of society. In early youth he was lively, and eager in the acquisition of knowledge. He never attended a public school; but was instructed in the ancient and modern languages, as well as in several branches of mathematics, and the arts necessarily connected with that science, by Mr Wingate, a man of

considerable parts and learning, who spent many years as preceptor or private tutor to Mr Home.

After studying, with acuteness and diligence, at the university of Edinburgh, the civil law, and the municipal law of his own country, Mr Home early perceived that a knowledge of these alone is not sufficient to make an accomplished lawyer. An acquaintance with the forms and practical business of courts, and especially of the supreme court, as a member of which he was to seek for fame and emolument, he considered as essentially necessary to qualify him to be a complete barrister. He accordingly attended for some time the chamber of a writer to the signet, where he had an opportunity of learning the styles of legal deeds, and the modes of conducting different species of business. This wise step, independently of his great genius and unwearied application, procured him, after his admission to the bar, peculiar respect from the court, and proportional employment in his profession of an advocate. Whoever peruses the law-papers composed by Mr Home when a young man, will perceive an uncommon elegance of style, besides great ingenuity of reasoning, and a thorough knowledge of the law and constitution of his country. These qualifications, together with the strength and vivacity of his natural abilities, soon raised him to be an ornament to the Scottish bar; and, on the 2d day of February 1752, he was advanced to the bench as one of the judges of the court of session, under the title of *Lord Kames*.

Before this period, however, notwithstanding the unavoidable labours of his profession, Mr Home had favoured the world with several useful and ingenious works. In the year 1728, he published *Remarkable Decisions of the Court of Session from 1716 to 1728*, in one vol. folio.—In 1732 appeared *Essays upon several subjects in law, viz. Jus tertii; Beneficium cedendarum actionum; Vinco Vincentem; and Prescription*; in one volume 8vo. This first produce of his original genius, and of his extensive views, excited not only the attention, but the admiration of the judges, and of all the other members of the college of justice. This work was succeeded, in the year 1741, by *Decisions of the Court of Session from its first institution to the year 1740, abridged and digested under proper heads, in form of a Dictionary*, in two volumes folio: A very laborious work, and of the greatest utility to every practical lawyer. In 1747 appeared *Essays upon several subjects concerning British Antiquities, viz. 1. Introduction of the feudal law into Scotland. 2. Constitution of parliament. 3. Honour, Dignity. 4. Succession, or Descent; with an appendix upon hereditary and indefeasible right, composed anno 1745, and published 1747*, in one volume 8vo. In a preface to this work, Lord Kames informs us, that in the years 1745 and 1746, when the nation was in great suspense and distraction, he retired to the country; and in order to banish as much as possible the uneasiness of his mind, he contrived the plan, and executed this ingenious performance.

Though not in the order of time, we shall continue the list of all our author's writings on law, before we proceed to his productions on other subjects. In 1757, he published *The Statute law of Scotland abridged, with historical notes*, in one volume 8vo; a most useful and laborious work. In the year 1759, he presented to the public a new work under the title of *Historical*

Home.

Home. *rical Law Tracts*, in one vol. 8vo. It contains fourteen interesting tracts, viz. History of the Criminal Law:—History of Promises and Covenants:—History of Property:—History of Securities upon and for Payment of Debt:—History of the Privilege which an Heir-apparent in a feudal holding has to continue the Possession of his Ancestor:—History of Regalities, and of the Privilege of repledging:—History of Courts:—History of Brieves:—History of Process in absence:—History of Execution against Moveables and Land for Payment of Debt:—History of Personal Execution for Payment of Debt:—History of Execution for obtaining Payment after the Death of the Debtor:—History of the limited and universal Representation of Heirs:—Old and New Extent. In 1760, he published, in one volume folio, *The principles of Equity*; a work which shows both the fertility of the author's genius and his indefatigable application. In 1766, he gave to the public another volume in folio of *Remarkable Decisions of the Court of Session*, from 1730 to 1752. In 1777, appeared his *Elucidations respecting the Common and Statute Law of Scotland*, in one volume 8vo. This book contains many curious and interesting remarks upon some intricate and dubious points which occur in the law of Scotland. In 1780, he published a volume in folio of *Select Decisions of the Court of Session from 1752 to 1768*.

From this sketch of Lord Kames's compositions and collections with a view to improve and elucidate the laws of Scotland, the reader may form some idea of his great industry, and of his anxious desire to promote the honour and welfare of his country. It remains to be remarked, that in the supreme court there, the law-writings of Lord Kames are held in equal estimation, and quoted with equal respect, as those of Coke or Blackstone in the courts of England.

Lord Kames's mind was very much inclined to metaphysical disquisitions. When a young man, in order to improve himself in his favourite study, he corresponded with the famous Berkeley bishop of Cloyne, Dr Butler bishop of Durham, Dr Samuel Clark, and many other ingenious and learned men both in Britain and Ireland. The letters of correspondence, we are happy to learn, have been carefully preserved by his son and heir George Home-Drummond, Esq; of Blair-Drummond.

The year 1751 gave birth to the first fruits of his Lordships metaphysical studies, under the title of *Essays on the Principles of Morality and natural Religion*, in two parts. Though a small volume, it was replete with ingenuity and acute reasoning, excited general attention, and gave rise to much controversy. It contained, in more explicit terms than perhaps any other work of a religious theist then known in Scotland, the doctrine which has of late made so much noise under the appellation of *philosophical necessity*. The same thing had indeed been taught by Hobbes, by Collins, and by the celebrated David Hume, Esq; but as those authors either were professed infidels, or were supposed to be such, it excited, as coming from them, no wonder, and provoked for a time very little indignation. But when a writer, who exhibited no symptoms of extravagant scepticism, who intimated nothing against the truth of revelation in general, and who inculcated with earnestness the great duties of morality and natural religion, advanced

at the same time so uncommon a doctrine as that of Home. *necessity*; a number of pens were immediately drawn against him, and for a while the work and its author were extremely obnoxious to a great part of the Scottish nation. On the other hand, there were some, and those not totally illiterate, who, confounding *necessity* with *predestination*, complimented Mr Home on his masterly defence of the established faith: and though between these two schemes there is no sort of resemblance, except that the future happiness or misery of all men is, according to both, certainly fore-known and appointed by God; yet we remember, that a professor in a dissenting academy so far mistook the one for the other, that he recommended to his pupils the *Essays on morality and natural religion*, as containing a complete vindication of the doctrine of Calvin. For this mistake he was dismissed from his office, and excluded from the communion of the sect to which he belonged. Lord Kames, like many other great and good men, continued a Necessarian to the day of his death; but in a subsequent edition of the essays, he exhibited a remarkable proof of his candor and liberality of sentiment, by altering the expressions, which, contrary to his intention, had given such general offence.

In 1761, he published an *Introduction to the Art of Thinking*, in one volume 12mo. This small but valuable book was originally intended for the instruction of his own family. The plan of it is both curious, amusing, and highly calculated to catch the attention and to improve the minds of youth. It consists of maxims collected from Rochefoucault and many other authors. To illustrate these maxims, and to rivet their spirit and meaning in the minds of young persons, his Lordship has added to most of them beautiful stories, fables, and historical anecdotes.

In the department of belles lettres, his *Elements of Criticism* appeared in 1762, in three volumes 8vo. This valuable work is the first and a most successful attempt to show, that the art of criticism is founded on the principles of human nature. Such a plan, it might be thought, should have produced a dry and phlegmatic performance. Lord Kames, on the contrary, from the sprightliness of his manner of treating every subject he handled, has rendered the *Elements of Criticism* not only highly instructive, but one of the most entertaining books in our language. Before this work was published, Rollin's *Belles Lettres*, a dull performance, from which a student could derive little advantage, was universally recommended as a standard; but, after the *Elements of Criticism* were presented to the public, Rollin instantly vanished, and gave place to greater genius and greater utility. With regard to real instruction and genuine taste in composition of every kind, a student, a gentleman, or a scholar, can in no language find such a fertile field of information. Lord Kames, accordingly, had the happiness of seeing the good effects of his labours, and of enjoying for twenty years a reputation which he so justly merited.

A still farther proof of the genius and various pursuits of this active mind was given in the year 1772, when his Lordship published a work in one volume 8vo, under the title of *The Gentleman Farmer, being an attempt to improve Agriculture by subjecting it to the test of rational principles*. Our limits do not permit us to give details: but, with regard to this book, we must

Home.

must inform the public, that all the intelligent farmers in Scotland uniformly declare, that, after perusing Young, Dickson, and a hundred other writers on agriculture, Lord Kames's *Gentleman Farmer* contains the best practical and rational information on the various articles of husbandry which can any where be obtained. As a practical farmer, Lord Kames has given many obvious proofs of his skill. After he succeeded, in right of his lady, to the ample estate of Blair-Drummond in the county of Perth, he formed a plan for turning a large moss, consisting of at least 1500 acres, into arable land. His Lordship had the pleasure, before he died, to see the plan successfully, though only partially, executed. The same plan is now carrying on in a much more rapid manner by his son George Drummond, Esq. But as this is not a proper place for details of this nature, we must refer the reader to the article Moss; where a particular account of this extraordinary, but extensively useful, operation shall be given.

In the year 1773, Lord Kames favoured the world with *Sketches of the History of Man*, in 2 vols 4to. This work consists of a great variety of facts and observations concerning the nature of man; the produce of much and profitable reading. In the course of his studies and reasonings, he had amassed a vast collection of materials. These, when considerably advanced in years, he digested under proper heads, and submitted them to the consideration of the public. He intended that this book should be equally intelligible to women as to men; and, to accomplish this end, when he had occasion to quote ancient or foreign books, he uniformly translated the passages. The *Sketches* contain much useful information; and, like all his Lordship's other performances, are lively and entertaining.

We now come to Lord Kames's last work, to which he modestly gives the title of *Loose Hints upon Education, chiefly concerning the Culture of the Heart*. It was published in the year 1781, in one vol. 8vo, when the venerable and astonishing author was in the 85th year of his age. Though his Lordship chose to call them *Loose Hints*, the intelligent reader will perceive in this composition an uncommon activity of mind at an age so far advanced beyond the usual period of human life, and an earnest desire to form the minds of youth to honour, to virtue, to industry, and to a veneration of the Deity.

Beside the books we have enumerated, Lord Kames published many temporary and fugitive pieces in different periodical works. In the *Essays Physical and Literary*, published by a society of gentlemen in Edinburgh, we find compositions of his Lordship *On the Laws of Motion, On the Advantages of Shallow Ploughing*, and on *Evaporation*; all of which exhibit evident marks of genius and originality of thinking.

How a man employed through life in public business,
N^o 156.

and in business of the first importance, could find leisure for so many different pursuits, and excel in them (A), it is not easy for a meaner mind to form even a conception. Much, no doubt, is to be attributed to the superiority of his genius; but much must likewise have been the result of a proper distribution of his time. He rose early; when in the vigour of life at four o'clock, in old age at six; and studied all morning. When the court was sitting, the duties of his office employed him from eight or nine till twelve or one; after which, if the weather permitted, he walked for two hours with some literary friends, and then went home to dinner. Whilst he was on the bench, and we believe when he was at the bar, he neither gave nor accepted invitations to dinner during the *term* or *session*; and if any friend came uninvited to dine with him, his Lordship displayed his usual cheerfulness and hospitality, but always retired with his clerk as soon as he had drunk a very few glasses of wine, leaving his company to be entertained by his lady. The afternoon was spent as the morning had been, in study. In the evening he went to the theatre or the concert, from which he returned to the society of some men of learning, with whom he sat late, and displayed such talents for conversation as are not often found. It is observed by a late celebrated author, that "to read, write, and converse, in due proportions, is the business of a man of letters; and that he who hopes to look back hereafter with satisfaction upon past years, must learn to know the value of single minutes, and endeavour to let no particle of time fall useless to the ground." It was by practising these lessons that Lord Kames rose to literary eminence, in opposition to all the obstacles which the tumult of public business could place in his way.

To give a proper delineation of the public and private character of Lord Kames, would far exceed our limits. The writer of this article, however, who had the honour of an intimate acquaintance with this great and good man for more than twenty years, must be indulged in adding a few facts which fell under his own observation.

Lord Kames was remarkable for public spirit, to which he conjoined activity and great exertion. He for a long tract of time had the principal management of all the societies and boards for promoting the trade, fisheries, and manufactures, in Scotland. As conducive to those ends, he was a strenuous advocate for making and repairing turnpike roads through every part of the country. He had likewise a chief lead in the distribution and application of the funds arising from the estates in Scotland which had unfortunately been annexed to the crown. He was no less zealous in supporting, both with his writings and personal influence, literary associations. He was in some measure the parent of what was called the *Physical and Literary Society*. This society was afterwards incorporated

(A) Upon reflecting on the studiousness of Lord Kames's disposition, and his numerous literary productions, the reader will naturally recal to his mind a striking similarity between his Lordship and the laborious Pliny the Elder. In a letter from Pliny the Younger to Macer, the following passage occurs, which is equally applicable to both: *Nonne videtur tibi, recordanti quantum legerit, quantum scripserit, nec in officiis ullis, nec in amicitia principum fuisse?* which is thus translated by Melmoth: "When you reflect on the books he has read and the volumes he has written, are you not inclined to suspect, that he never was engaged in the affairs of the public, or the service of his prince?"

HOMER. rated into the *Royal Society of Edinburgh*, which received a charter from the crown, and which is daily producing marks of genius, as well as works of real utility.

As a private and domestic gentleman, Lord Kames was admired by both sexes. The vivacity of his wit and of his animal spirits, even when advanced in years, rendered his company not only agreeable, but greatly solicited by the literati, and courted by ladies of the highest rank and accomplishments. He told very few stories; and rarely, if ever, repeated the same story to the same person. From the necessity of retailing anecdotes, the miserable refuge of those who, without genius, attempt to shine in conversation, the abundance of his own mind set him free; for his wit or his learning always suggested what the occasion required. He could with equal ease and readiness combat the opinions of a metaphysician, unravel the intricacies of law, talk with a farmer on improvements in agriculture, or estimate with a lady the merits of the dress in fashion. Instead of being jealous of rivals, the characteristic of little minds, Lord Kames fostered and encouraged every symptom of merit that he could discover in the scholar, or in the lowest mechanic. Before he succeeded to the estate of Blair-Drummond, his fortune was small. Notwithstanding this circumstance, he, in conjunction with Mrs Drummond, his respectable and accomplished spouse, did much more service to the indigent than most families of greater opulence. If the present necessity was pressing, they gave money. They did more: When they discovered that male or female petitioners were capable of performing any art or labour, both parties exerted themselves in procuring that species of work which the poor people could perform. In cases of this kind, which were very frequent, the lady took charge of the women and his Lordship of the men. From what has been said concerning the various and numerous productions of his genius, it is obvious that there could be few idle moments in his long protracted life. His mind was incessantly employed; either teeming with new ideas, or pursuing active and laborious occupations. At the same time, with all this intellectual ardour, one great feature in the character of Lord Kames, beside his literary talents and his public spirit, was a remarkable innocency of mind. He not only never indulged in detraction, but when any species of scandal was exhibited in his company, he either remained silent, or endeavoured to give a different turn to the conversation. As natural consequences of this amiable disposition, he never meddled with politics, even when parties ran to indecent lengths in this country; and, what is still more remarkable, he never wrote a sentence, notwithstanding his numerous publications, without a direct and a manifest intention to benefit his fellow creatures. In his temper he was naturally warm, though kindly and affectionate. In the friendships he formed, he was ardent, zealous, and sincere. So far from being inclined to irreligion, as some ignorant bigots insinuated, few men possessed a more devout habit of thought. A constant sense of Deity, and a veneration for Providence, dwelt upon his mind. From this source arose that propensity which appears in all his writings, of investigating final causes, and tracing the wisdom of the Supreme Author of nature. But here we must stop. Lord Kames, to the

VOL. VIII. Part II.

great regret of the public, died on the 27th day of December 1782. As he had no marked disease but the debility necessarily resulting from extreme old age, a few days before his death he went to the Court of Session, addressed all the judges separately, told them he was speedily to depart, and took a solemn and an affectionate farewell.

HOMER, the prince of the Greek poets, flourished, according to Dr Blair, about 900 B. C. according to Dr Priestley 850, according to the Arundelian marbles 300, after the taking of Troy; and agreeable to them all, above 400 years before Plato and Aristotle. Seven cities disputed the glory of having given him birth, viz. Smyrna, Rhodes, Colophon, Salamis, Chios, Argos, and Athens; which has been expressed by the following distich:

*Smyrna, Rhodes, Colophon, Salamis, Chios, Argos, Athens;
Orbis de patria certat, Homere, tua.*

We have nothing that is very certain in relation to the particulars of his life. The most regular account is that which goes under the name of Herodotus, and is usually printed with his history: and though it is generally supposed to be a spurious piece, yet as it is ancient, was made use of by Strabo, and exhibits that idea which the later Greeks, and the Romans in the age of Augustus, entertained of Homer, we must content ourselves with giving an abstract of it.

A man of Magnesia, whose name was *Menalippus*, went to settle at Cumæ, where he married the daughter of a citizen called *Homyres*, and had by her a daughter called *Critheis*. The father and mother dying, the young woman was left under the tuition of Cleonax her father's friend, and suffering herself to be deluded was got with child. The guardian, though his care had not prevented the misfortune, was however willing to conceal it; and therefore sent Critheis to Smyrna, which was then building, 18 years after the founding of Cumæ, and about 168 after the taking of Troy. Critheis being near her time, went one day to a festival, which the town of Smyrna was celebrating on the banks of the river Meles; where her pains coming upon her, she was delivered of Homer, whom she called *Melesigenes*, because he was born on the banks of that river. Having nothing to maintain her, she was forced to spin: and a man of Smyrna called *Phemius*, who taught literature and music, having often seen Critheis, who lodged near him, and being pleased with her housewifery, took her into his house to spin the wool he received from his scholars for their schooling. Here she behaved herself so modestly and discreetly, that Phemius married her; and adopted her son, in whom he discovered a wonderful genius, and the best natural disposition in the world. After the death of Phemius and Critheis, Homer succeeded to his father-in-law's fortune and school; and was admired, not only by the inhabitants of Smyrna, but by strangers, who resorted from all parts to that place of trade. A shipmaster called *Mentes*, who was a man of learning and a lover of poetry, was so taken with Homer, that he persuaded him to leave his school, and to travel with him. Homer, who had then begun his poem of the Iliad, and thought it of great consequence to see the places he should have occasion to treat of, embraced the opportunity. He embarked with Mentes, and during their several voyages never failed carefully

4 K to

Homer.

to note down all that he thought worth observing. He travelled into Egypt; from whence he brought into Greece the names of their gods, the chief ceremonies of their worship, and a more improved knowledge in the arts than what prevailed in his own country. He visited Africa and Spain; in his return from whence he touched at Ithaca, where he was much troubled with a rheum falling upon his eyes. Mentès being in haste to take a turn to Leucadia his native country, left Homer well recommended to Mentor, one of the chief men of the island of Ithaca, who took all possible care of him. There Homer was informed of many things relating to Ulysses, which he afterwards made use of in composing his *Odyssey*. Mentès returning to Ithaca, found Homer cured. They embarked together; and after much time spent in visiting the coasts of Peloponnesus and the islands, they arrived at Colophon, where Homer was again troubled with the defluxion upon his eyes, which proved so violent, that he is said to have lost his sight. This misfortune made him resolve to return to Smyrna, where he finished his *Iliad*. Some time after, the ill posture of his affairs obliged him to go to Cumæ, where he hoped to have found some relief. Here his poems were highly applauded: but when he proposed to immortalize their town, if they would allow him a salary, he was answered, that "there would be no end of maintaining all the *'Ounpoi* or "blind men;" and hence got the name of *Homer*. He afterwards wandered through several places, and stopped at Chios, where he married, and composed his *Odyssey*. Some time after, having added many verses to his poems in praise of the cities of Greece, especially of Athens and Argos, he went to Samos, where he spent the winter, singing at the houses of the great men, with a train of boys after him. From Samos he went to Io, one of the Sporades, with a design to continue his voyage to Athens; but landing by the way at Chios, he fell sick, died, and was buried on the sea-shore.

The only incontestable works which Homer has left behind him are the *ILIAD* and *ODYSSEY*. The *Batrachomyomachia*, or battle of the frogs and mice, has been disputed. The hymns have been disputed also, and attributed by the scholiasts to Cynæthus the rhapsodist: but neither Thucydides, Lucian, nor Pausanias, have scrupled to cite them as genuine. Many other pieces are ascribed to him: epigrams, the *Eartiges*, the *Cecropes*, the destruction of *Oechalia*, of which only the names are remaining.

Nothing was ever comparable to the clearness and majesty of Homer's style; to the sublimity of his thoughts; to the strength and sweetness of his verses. All his images are striking; his descriptions just and exact; the passions so well expressed, and nature so just and finely painted, that he gives to every thing motion, life, and action. But he more particularly excels in invention, and in the different characters of his heroes, which are so varied, that they affect us in an inexpressible manner. In a word, the more he is read by a person of good taste, the more he is admired. Nor are his works to be esteemed merely as entertaining poems, or as the monuments of a sublime and varied genius. He was in general so accurate with respect to costume, that he seldom mentioned persons or things that we may not conclude to have been known during

the times of which he writes; and it was Mr Pope's opinion, that his account of people, princes, and countries, was purely historical, founded on the real transactions of those times, and by far the most valuable piece of history and geography left us concerning the state of Greece in that early period. His geographical divisions of that country were thought so exact, that we are told of many controversies concerning the boundaries of Grecian cities which have been decided upon the authority of his poems.

Alcibiades gave a rhetorician a box on the ear for not having Homer's writings in his school. Alexander was ravished with them, and commonly placed them under his pillow with his sword: he inclosed the *Iliad* in the precious casket that belonged to Darius; "in order (said he to his courtiers) that the most perfect production of the human mind might be inclosed in the most valuable casket in the world." And one day seeing the tomb of Achilles in Sigæa, "Fortunate hero! (cried he), thou hast had a Homer to sing thy victories!" Lycurgus, Solon, and the kings and princes of Greece, set such a value on Homer's works, that they took the utmost pains in procuring correct editions of them, the most esteemed of which is that of Aristarchus. Didymus was the first who wrote notes on Homer; and Eustathius, archbishop of Thessalonica, in the 12th century, is the most celebrated of his commentators. Mr Pope has given an elegant translation of the *Iliad*, adorned with the harmony of poetic numbers; and Mad. Dacier has translated both the *Iliad* and *Odyssey* in prose.

Those who desire to know the several editions of Homer, and the writers who have employed themselves on the works of that great poet, may consult Fabricius, in the first volume of his *Bibliotheca Græca*.

A very singular discovery, however, which was made a few years ago in Russia, deserves to be here mentioned, together with the circumstances that attended it. Christian Frederic Matthæi, who had been educated by the learned Ernesti, and did credit to the instructions of that celebrated master by the great erudition that he displayed, being invited to settle at Moscow, and to assist in a plan of literature for which his abilities and acquisitions eminently qualified him; on his arrival at that city was informed, equally to his astonishment and satisfaction, that a very copious treasure of Greek manuscripts was deposited in the library of the Holy synod, which no person in that country had either the abilities to make use of, or the curiosity to examine. Struck with the relation of a circumstance so unexpected, and at the same time so peculiarly agreeable to his classical taste, he immediately seized the opportunity that was fortunately offered him, to explore this repository of hidden treasure. After having examined several curious books, he discovered a manuscript copy of the works of Homer, written about the conclusion of the 14th century, but evidently a transcript from a very ancient and most valuable copy, which, besides the *Iliad* and the *Odyssey*, contains also 16 of the hymns, which have been long published under the name of *Homer*. Nor was this all. Twelve lines of a lost hymn to Bacchus, and the hymn to Ceres, which was also lost, were preserved in this curious and long unnoticed manuscript. The hymn to Ceres appears to be entire, excepting a few lines towards the close: and it is surely remarkable, that

Homer.

Homer. that a Greek poem, attributed to Homer, which had been lost for ages, should be at length discovered in Muscovy, the rudest and most unclassical country in Europe. M. Matthæi, exulting in an acquisition so unexpected, and at the same time so valuable, communicated it, with singular disinterestedness, to his learned friend M. Ruhnkenius, with whose talents and extraordinary erudition he was well acquainted, that this gentleman might present it to the world without those delays which would probably have retarded the publication of it at Moscow. He was rather induced to employ M. Ruhnkenius in the publication of this curious and beautiful remnant of antiquity, because he knew that this gentleman had been particularly engaged in the study of the hymns of Homer, in order to give the public a complete edition of them. The hymn to Ceres, and the fragment of the hymn to Bacchus, were printed in 1780 at Leyden, under the care of M. Ruhnkenius; who has added some very valuable notes and observations on the hymn to Ceres, which tend to illustrate its beauties, and to throw a light on some of its obscurities. The learned editor observes, that nothing was more distant from his expectations than the discovery of this hymn to Ceres. He knew indeed that a poem bearing that title, and ascribed to Homer, existed in the second century; but as it had long been considered as irretrievably lost, he had formed no hopes of ever seeing it rescued from the obscurity to which it had been consigned. He acknowledges, that he has many doubts with respect to the high and illustrious origin ascribed to this hymn: but as no positive external evidence can be produced to determine the point, he chooses to rest his argument on what appears to him the more certain ground of internal proof; and observes, that though the poem be exquisitely beautiful, yet that it is evidently deficient in some of Homer's more striking and predominant characteristics. It wants his energy and spirit; that vigour, that inspiration, which animate and give an irresistible power, as well as an enchanting beauty, to the poems of that sublime and inimitable bard. This opinion, as we have already seen, hath been given by other critics of all the hymns of Homer. But though M. Ruhnkenius is not inclined to attribute the hymn of Ceres to Homer, he yet acknowledges, that the structure of its language is founded on the model of that great poet, and he hesitates not to give it the honour of very high antiquity. He is of opinion, that it was written immediately after Homer, or at least in the age of Hesiod: and he congratulates the age on the discovery of so curious a poem, rescued by mere accident from the darkest retreats of oblivion, and perhaps but at a slight distance from inevitable perdition. He deems it to be an acquisition, not only calculated to gratify the curiosity of the connoisseurs in classic antiquity, or to entertain those lovers of Greek poetry whose studies are made subservient to a refined and elegant species of amusement, but he also esteems it to be of particular use to the critic, as it tends to illustrate some obscure passages both in the Greek and Latin poets.

HOMER, OMER, or CHOMER, a Jewish measure, containing the tenth part of the epha. See **CORUS** and **MEASURE**.

HOMESOKEN. See **HAMESECKEN**.

HOMICIDE, signifies in general, the taking away of any person's life. It is of three kinds; *justifiable,*

excusable, and *felonious*. The first has no share of Homicide. guilt at all; the second very little; but the third is the highest crime against the law of nature that man is capable of committing.

I. Justifiable homicide is of divers kinds.

1. Such as is owing to some unavoidable necessity, without any will, intention, or desire, and without any inadvertence or negligence, in the party killing, and therefore without any shadow of blame; as, for instance, by virtue of such an office as obliges one, in the execution of public justice, to put a malefactor to death, who hath forfeited his life by the laws and verdict of his country. This is an act of necessity, and even of civil duty; and therefore not only justifiable, but commendable, where the law requires it. But the law must require it, otherwise it is not justifiable: therefore wantonly to kill the greatest of malefactors, a felon, or a traitor, attainted or outlawed, deliberately, uncompelled, and extrajudicially, is murder. And farther, if judgment of death be given by a judge not authorized by lawful commission, and execution is done accordingly, the judge is guilty of murder. Also such judgment, when legal, must be executed by the proper officer, or his appointed deputy; for no one else is required by law to do it, which requisition it is that justifies the homicide. If another person doth it of his own head, it is held to be murder: even though it be the judge himself. It must farther be executed, *servato juris ordine*; it must pursue the sentence of the court. If an officer beheads one who is adjudged to be hanged, or *vice versa*, it is murder: for he is merely ministerial, and therefore only justified when he acts under the authority and compulsion of the law. But, if a sheriff changes one kind of punishment for another, he then acts by his own authority, which extends not to the commission of homicide: and besides, this licence might occasion a very gross abuse of his power. The king indeed may remit part of a sentence, as in the case of treason, all but the beheading: but this is no change, no introduction of a new punishment; and in the case of felony, where the judgment is *to be hanged*, the king (it hath been said) cannot legally order even a peer to be beheaded.

Again: In some cases homicide is justifiable, rather by the *permission*, than by the absolute *command*, of the law: either for the *advancement* of public justice, which without such indemnification would never be carried on with proper vigour; or, in such instances where it is committed for the *prevention* of some atrocious crime, which cannot otherwise be avoided.

2. Homicides, committed for the *advancement* of public justice, are, 1. Where an officer, in the execution of his office, either in a civil or criminal case, kills a person that assaults and resists him. 2. If an officer, or any private person, attempts to take a man charged with felony, and is resisted; and, in the endeavour to take him, kills him. 3. In case of a riot, or rebellious assembly, the officers endeavouring to disperse the mob are justifiable in killing them, both at common law, and by the riot act, 1 Geo. 1. c. 5. 4. Where the prisoners in a gaol, or going to gaol, assault the gaoler or officer, and he in his defence kills any of them, it is justifiable, for the sake of preventing an escape. 5. If trespassers in forests, parks, chases, or warrens, will not surrender themselves to the keepers, they may be slain; by virtue of the statute

Homicide. 21 Edward I. ft. 2. *de malefactoribus in parais*, and 3 & 4 W. & M. c. 10. But, in all these cases, there must be an apparent necessity on the officer's side; viz. that the party could not be arrested or apprehended, the riot could not be suppressed, the prisoners could not be kept in hold, the deer-stealers could not but escape, unless such homicide were committed; otherwise, without such absolute necessity, it is not justifiable. 6. If the champions in a trial by battle killed either of them the other, such homicide was justifiable, and was imputed to the just judgment of God, who was thereby presumed to have decided in favour of the truth.

3. In the next place, such homicide as is committed for the *prevention* of any forcible and atrocious crime, is justifiable by the law of nature; and also by the law of England, as it stood so early as the time of Bracton, and as it is since declared by stat. 24 H. VIII. c. 5. If any person attempts a robbery or murder of another, or attempts to break open a house *in the night-time* (which extends also to an attempt to burn it), and shall be killed in such attempt, the slayer shall be acquitted and discharged. This reaches not to any crime unaccompanied with force, as picking of pockets; or to the breaking open of any house *in the day-time*, unless it carries with it an attempt of robbery also. So the Jewish law, which punished no theft with death, makes homicide only justifiable in case of *nocturnal* house-breaking: "if a thief be found breaking up, and he be smitten that he die, no blood shall be shed for him; but if the sun be risen upon him, there shall blood be shed for him; for he should have made full restitution." At Athens, if any theft was committed by night, it was lawful to kill the criminal, if taken in the fact: and, by the Roman law of the twelve tables, a thief might be slain by night with impunity; or even by day, if he armed himself with any dangerous weapon: which amounts very nearly to the same as is permitted by our own constitutions.

The Roman law also justifies homicide, when committed in defence of the chastity either of one's self or relations: and so also, according to Selden, stood the law in the Jewish republic. The English law likewise justifies a woman killing one who attempts to ravish her: and so too the husband or father may justify killing a man, who attempts a rape upon his wife or daughter; but not if he takes them in adultery by consent; for the one is forcible and felonious, but not the other. And there is no doubt but the forcibly attempting a crime, of a still more detestable nature, may be equally resisted by the death of the unnatural aggressor. For the one uniform principle that runs through our own, and all other laws, seems to be this: That where a crime, in itself capital, is endeavoured to be committed by force, it is lawful to repel that force by the death of the party attempting. But we must not carry this doctrine to the same visionary length that Mr Locke does; who holds, "that all manner of force without right upon a man's person, puts him in a state of war with the aggressor; and, of consequence, that, being in such a state of war, he may lawfully kill him that puts him under this unnatural restraint." However just this conclusion may be in a state of uncivilized nature, yet the law of Eng-

land, like that of every other well-regulated community, is too tender of the public peace, too careful of the lives of the subjects, to adopt so contentious a system; nor will suffer with impunity any crime to be *prevented* by death, unless the same, if committed, would also be *punished* by death.

In these instances of *justifiable* homicide, it may be observed, that the slayer is in no kind of fault whatsoever, not even in the minutest degree: and is therefore to be totally acquitted and discharged, with commendation rather than blame. But that is not quite the case in *excusable* homicide, the very name whereof imports some fault, some error, or omission; so trivial, however, that the law excuses it from the guilt of felony, though in strictness it judges it deserving of some little degree of punishment.

II. Excusable homicide is of two sorts; either *per infortunium*, by misadventure; or *se defendendo*, upon a principle of self preservation. We will first see wherein these two species of homicide are distinct, and then wherein they agree.

1. Homicide *per infortunium*, or misadventure, is where a man, doing a lawful act, without any intention of hurt, unfortunately kills another: as where a man is at work with a hatchet, and the head thereof flies off and kills a stander-by; or, where a person, qualified to keep a gun, is shooting at a mark, and undesignedly kills a man: for the act is lawful, and the effect is merely accidental. So where a parent is moderately correcting his child, a master his apprentice or scholar, or an officer punishing a criminal, and happens to occasion his death, it is only misadventure; for the act of correction was lawful: but if he exceeds the bounds of moderation, either in the manner, the instrument, or the quantity of punishment, and death ensues, it is manslaughter at least, and in some cases (according to the circumstances) murder; for the act of immoderate correction is unlawful. Thus by an edict of the emperor Constantine, when the rigour of the Roman law with regard to slaves began to relax and soften, a master was allowed to chastise his slave with rods and imprisonment, and if death accidentally ensued, he was guilty of no crime: but if he struck him with a club or a stone, and thereby occasioned his death, or if in any other yet grosser manner "*immoderate suo jure utatur, tunc reus homicidii fit.*"

But to proceed. A tilt or tournament, the martial diversion of our ancestors, was however an unlawful act; and so are boxing and sword-playing, the succeeding amusement of their posterity: and therefore, if a knight in the former case, or a gladiator in the latter, be killed, such killing is felony of manslaughter. But if the king command or permit such diversion, it is said to be only misadventure; for then the act is lawful: In like manner as, by the laws both of Athens and Rome, he who killed another in the *pancratium*, or public games, authorised or permitted by the state, was not held to be guilty of homicide. Likewise to whip another's horse, whereby he runs over a child and kills him, is held to be accidental in the rider, for he has done nothing unlawful; but manslaughter in the person who whipped him, for the act was a trespass, and at best a piece of idleness, of inevitably dangerous consequence. And in general, if death ensues in consequence of an idle, dangerous, and

Homicide. and unlawful sport, as shooting or casting stones in a town, or the barbarous diversion of cock-throwing; in these and similar cases, the slayer is guilty of manslaughter, and not misadventure only; for these are unlawful acts.

2. Homicide in *self-defence*, or *se defendendo*, upon a sudden affray, is also excusable rather than justifiable, by the English law. This species of self-defence must be distinguished from that just now mentioned, as calculated to hinder the perpetration of a capital crime; which is not only a matter of excuse, but of justification. But the self-defence which we are now speaking of, is that whereby a man may protect himself from an assault, or the like, in the course of a sudden brawl or quarrel, by killing him who assaults him. And this is what the law expresses by the word *chance-medley*, or (as some rather choose to write it) *chaud-medley*; the former of which in its etymology signifies a *casual* affray, the latter an affray in the *heat* of blood or passion: both of them of pretty much the same import; but the former is in common speech too often erroneously applied to any manner of homicide by misadventure; whereas it appears by the statute 24 H. VIII. c. 5. and our ancient books, that it is properly applied to such killing as happens in self-defence upon a sudden rencounter. The right of natural defence does not imply a right of attacking: for, instead of attacking one another for injuries past or impending, men need only have recourse to the proper tribunals of justice. They cannot therefore legally exercise this right of preventive defence, but in sudden and violent cases; when certain and immediate suffering would be the consequence of waiting for the assistance of the law. Wherefore, to excuse homicide by the plea of self-defence, it must appear that the slayer had no other possible means of escaping from his assailant.

In some cases this species of homicide (upon *chance-medley* in self-defence) differs but little from manslaughter, which also happens frequently upon *chance-medley* in the proper legal sense of the word. But the true criterion between them seems to be this; when both parties are actually combating at the time when the mortal stroke is given, the slayer is then guilty of manslaughter; but if the slayer hath not begun to fight, or (having begun) endeavours to decline any farther struggle, and afterwards, being closely pressed by his antagonist, kills him to avoid his own destruction, this is homicide excusable by self-defence. For which reason the law requires, that the person, who kills another in his own defence, should have retreated as far as he conveniently or safely can, to avoid the violence of the assault, before he turns upon his assailant; and that not fictitiously, or in order to watch his opportunity, but from a real tenderness of shedding his brother's blood. And though it may be cowardice, in time of war between two independent nations, to flee from an enemy; yet between two fellow-subjects, the law countenances no such point of honour: because the king and his courts are the *vindices injuriarum*, and will give to the party wronged all the satisfaction he deserves. In this the civil law also agrees with ours, or perhaps goes rather farther; "*qui cum aliter tueri se non possunt, damni culpam dederint, innoxii sunt.*" The party assaulted must therefore flee as far as he conveniently can, either by reason of some wall, ditch, or

other impediment; or as far as the fierceness of the assault will permit him; for it may be so fierce as not to allow him to yield a step, with manifest danger of his life, or enormous bodily harm; and then in his defence he may kill his assailant instantly. And this is the doctrine of universal justice, as well as of the municipal law.

And, as the *manner* of the defence, so is also the *time* to be considered: for if the person assaulted does not fall upon the aggressor till the affray is over, or when he is running away, this is revenge and not defence. Neither, under the colour of self-defence, will the law permit a man to screen himself from the guilt of deliberate murder: for if two persons, A and B, agree to fight a duel, and A gives the first onset, and B retreats as far as he safely can, and then kills A, this is murder; because of the previous malice and concerted design. But if A upon a sudden quarrel assaults B first, and, upon B's returning the assault, A really and *bona fide* flies; and, being driven to the wall, turns again upon B and kills him; this may be *se defendendo*, according to some of our writers; though others have thought this opinion too favourable: inasmuch as the necessity, to which he is at last reduced, originally arose from his own fault. Under this excuse of self-defence, the principal civil and natural relations are comprehended: therefore, master and servant, parent and child, husband and wife, killing an assailant in the necessary defence of each other respectively, are excused; the act of the relation assisting being construed the same as the act of the party himself.

There is one species of homicide *se defendendo*, where the party slain is equally innocent as he who occasions his death: and yet this homicide is also excusable from the great universal principle of self-preservation, which prompts every man to save his own life preferable to that of another, where one of them must inevitably perish. As, among others, in that case mentioned by lord Bacon, where two persons, being shipwrecked, and getting on the same plank, but finding it not able to save them both, one of them thrusts the other from it, whereby he is drowned. He who thus preserves his own life at the expence of another man's, is excusable through unavoidable necessity, and the principle of self-defence; since their both remaining on the same weak plank is a mutual, though innocent, attempt upon, and an endangering of, each other's life.

Let us next take a view of those circumstances wherein those two species of homicide, by misadventure and self-defence, agree; and those are in their blame and punishment. For the law sets so high a value upon the life of a man, that it always intends some misbehaviour in the person who takes it away, unless by the command or express permission of the law. In the case of misadventure, it presumes negligence, or at least a want of sufficient caution in him who was so unfortunate as to commit it; who therefore is not altogether faultless. And as to the necessity which excuses a man who kills another *se defendendo*, lord Bacon intitles it *necessitas culpabilis*, and thereby distinguishes it from the former necessity of killing a thief or a malefactor. For the law intends that the quarrel or assault arose from some unknown wrong, or some provocation, either in word or deed: and since in quarrels

Homicide.

quarrels both parties may be, and usually are, in some fault; and it scarce can be tried who was originally in the wrong; the law will not hold the survivor entirely guiltless. But it is clear, in the other case, that where I kill a thief who breaks into my house, the original default can never be upon my side. The law besides may have a farther view, to make the crime of homicide more odious, and to caution men how they venture to kill another upon their own private judgment; by ordaining, that he who slays his neighbour, without an express warrant from the law so to do, shall in no case be absolutely free from guilt.

Nor is the law of England singular in this respect. Even the slaughter of enemies required a solemn purgation among the Jews; which implies, that the death of a man, however it happens, will leave some stain behind it. And the Mosaiical law appointed certain cities of refuge for him "who killed his neighbour unawares; as if a man goeth into the wood with his neighbour to hew wood, and his hand fetcheth a stroke with the ax to cut down a tree, and the head slippeth from the helve, and lighteth upon his neighbour that he die, he shall flee into one of those cities and live." But it seems he was not held wholly blameless, any more than in the English law; since the avenger of blood might slay him before he reached his asylum, or if he afterwards stirred out of it till the death of the high priest. In the imperial law likewise casual homicide was excused, by the indulgence of the emperor signed with his own sign manual, "*adnotatione principis*;" otherwise, the death of a man, however committed, was in some degree punishable. Among the Greeks, homicide by misfortune was expiated by voluntary banishment for a year. In Saxony, a fine is paid to the kindred of the slain; which also, among the western Goths, was little inferior to that of voluntary homicide: and in France, no person is ever absolved in cases of this nature, without a largess to the poor, and the charge of certain masses for the soul of the party killed.

The penalty inflicted by our laws is said by Sir Edward Coke to have been anciently no less than death; which, however, is with reason denied by later and more accurate writers. It seems rather to have consisted in a forfeiture, some say of all the goods and chattel, others of only a part of them, by way of fine or *weregild*: which was probably disposed of, as in France, in *pious usus*, according to the humane superstition of the times, for the benefit of his soul who was thus suddenly sent to his account with all his imperfections on his head. But that reason having long ceased, and the penalty (especially if a total forfeiture) growing more severe than was intended, in proportion as personal property has become more considerable, the delinquent has now, and has had as early as our records will reach, a pardon and writ of restitution of his goods as a matter of course and right, only paying for suing out the same. And, indeed, to prevent this expense, in cases where the death has notoriously happened by misadventure or in self-defence, the judges will usually permit (if not direct) a general verdict of acquittal.

III. Felonious homicide is an act of a very different nature from the former, being the killing of a human creature, of any age or sex, without justification or

excuse. This may be done either by killing one's self, or another man: for the consideration of which, see the articles *SELF Murder*, *MURDER*, and *MANSLAUGHTER*.

HOMILY, in ecclesiastical writers, a sermon or discourse upon some point of religion, delivered in a plain manner, so as to be easily understood by the common people. The word is Greek, *ομιλία*; formed of *ομιλῶ*, *catus*, "assembly or council."

The Greek homily, says M. Fleury, signifies a familiar discourse, like the Latin *sermo*; and discourses delivered in the church took these denominations, to intimate, that they were not harangues or matters of ostentation and flourish, like those of profane orators, but familiar and useful discourses, as of a master to his disciples, or a father to his children.

All the homilies of the Greek and Latin fathers are composed by bishops. We have none of Tertullian, Clemens Alexandrinus, and many other learned persons; because, in the first ages, none but bishops were admitted to preach. The privilege was not ordinarily allowed to priests till toward the fifth century. St Chrysostom was the first presbyter that preached steadily. Origen and St Augustine also preached; but it was by a peculiar licence or privilege.

Photius distinguishes *homily* from *sermon*; in that the homily was performed in a more familiar manner, the prelate interrogating and talking to the people, and they in their turn answering and interrogating him, so that it was properly a conversation; whereas the sermon was delivered with more form, and in the pulpit, after the manner of the orators.

The practice of compiling homilies, which were to be committed to memory, and recited by ignorant or indolent priests, commenced towards the close of the 8th century; when Charlemagne ordered Paul Deacon and Alcuin to form homilies or discourses upon the Gospels and Epistles, from the ancient doctors of the church. This gave rise to that famous collection intitled the *Homiliarium of Charlemagne*, and which being followed as a model by many productions of the same kind, composed by private persons, from a principle of pious zeal, contributed much (says Mosheim) to nourish the indolence, and to perpetuate the ignorance of a worthless clergy.

There are still extant several fine homilies, composed by the ancient fathers, particularly St Chrysostom and St Gregory.

Clementine HOMILIES, in ecclesiastical history, are nineteen homilies in Greek, published by Cotelierius, with two letters prefixed; one of them written in the name of Peter, the other in the name of Clement, to James bishop of Jerusalem; in which last letter they are intitled Clement's Epitome of the Preaching and Travels of Peter. According to Le Clerc, these homilies were composed by an Ebionite in the second century; but Montfaucon supposes that they were forged long after the age of St Athanasius. Dr Lardner apprehends, that the Clementine homilies were the original or first edition of the Recognitions; and that they are the same with the work censured by Eusebius under the title of Dialogues of Peter and Apion.

HOMINE REPLEGIANDO, a writ for the bailing of a man out of prison when he is confined without commandment of the king or his judges, or for any cause that

Honan.

HOMMOC, a name given by mariners to a hillock or small eminence of land, resembling the figure of a cone, and appearing on the sea-coast of any country.

HOMO, MAN, is ranked by Linnæus under the order of primates; and characterised by having four parallel foreteeth both in the upper and lower jaw, and two mammae on the breast. The species, according to this author, are two, viz. the *homo sapiens*, and the *homo troglodytes*.

He subdivides the *homo sapiens* into five varieties, viz. the American, the European, the Asiatic, the African, and what he calls the *monstrous*. See **MAN**.

The *troglodytes*, or orang outang, is a native of Ethiopia, Java, and Amboina. His body is white; he walks erect; and is about one-half the ordinary human size. He generally lives about 25 years. He conceals himself in caves during the day, and searches for his prey in the night. He is said to be exceedingly sagacious, but is not endowed with the faculty of speech. See **TROGLODYTES**, **SIMIA**, and **COMPARATIVE ANATOMY**, p. 250, col. 2.

HOMOGENEOUS, or **HOMOGENEAL** (composed of the Greek *ὁμος* like, and *γενος* kind), is a term applied to various subjects, to denote, that they consist of similar parts, or of parts of the same nature and kind: in contradistinction to *heterogeneous*, where the parts are of different natures, &c.

HOMOLOGATION, in the civil law, the act of confirming or rendering a thing more valid and solemn, by publication, repetition, or recognition thereof.—The word comes from the Greek *ὁμολογια* “consent, assent;” formed of *ὁμος* *similis*, “like,” and *λογος*, of *λογειν*, *dicere*, “to say;” *q. d.* to say the same thing, to consent, agree.

HOMOLOGOUS, in geometry, an appellation given to the corresponding sides and angles of similar figures, as being proportional to each other.

HONAN, a province of China, bounded on the north by that of Ptecheli and Chanfi; on the west by Chanfi, on the south by Houquang, and on the east by Chantong. Every thing that can contribute to render a country delightful is found united in this province; the Chinese therefore call it *Tong-hoa* or *the middle flower*: it is indeed situated almost in the centre of China. The ancient emperors, invited by the mildness of the climate and the beauty of the country, fixed their residence here for some time. The abundance of its fruits, pastures, and corn, the effeminacy of its inhabitants (who are accounted extremely voluptuous), and lastly, the cheapness of provisions, have no doubt prevented trade from being so flourishing here as in the other provinces of the empire. The whole country is flat excepting towards the west, where there arises a long chain of mountains, covered with thick forests; and the land is in such a high state of cultivation, that those who travel through it imagine they are walking in an immense garden.—Besides the river Hoangho, which traverses this province, it is watered by a great number of springs and fountains; it has also a valuable lake, which invites to its banks a prodigious number of workmen, because its water has the property of communicating a lustre to silk, which can-

not be imitated. Exclusive of forts, castles, and places of strength, this province contains eight *fou* or cities of the first class, and 102 of the second and third. In one of these cities named *Nanyang*, is found a kind of serpent, the skin of which is marked with small white spots: the Chinese physicians steep it in wine, and use it afterwards as an excellent remedy against the palsy.

HONAN-Fou, a city of the above province, situated amidst mountains and between three rivers. The Chinese formerly believed this city to be the centre of the earth, because it was in the middle of their empire. Its jurisdiction is very extensive; for it comprehends one city of the second class and thirteen of the third: one of these cities named *Teng-fong-bien*, is famous on account of the tower erected by the celebrated Tcheou-kong for an observatory; there is still to be seen in it an instrument which he made use of to find the shadow at noon, in order to determine the latitude. This astronomer lived above a thousand years before the Christian era, and the Chinese pretend that he invented the mariner's compass.

HONDEKOOTER (Melchior), a famous Dutch painter born at Utrecht, excelled in painting animals, and especially birds. His father and grandfather were of the same profession, and their subjects the same. He was trained up to the art by his father; but surpassed not only him, but even the best of his contemporaries in a very high degree. Till he was seventeen years of age, he continued under the direction of his father, and accustomed himself to paint several sorts of birds; but particularly he was pleased to represent cocks, hens, ducks, chickens, and peacocks, which he described in an elegant variety of actions and attitudes.—After his father's death, which happened in 1653, he received some instructions from his uncle John Baptist Weenix; but his principal and best instructor was nature, which he studied with intense application. His pencil was wonderfully neat and delicate; his touch light; his colouring exceedingly natural, lively, and remarkably transparent; and the feathers of his fowls were expressed with such a swelling softness, as might readily and agreeably deceive the eye of any spectator. It is reported that he had trained up a cock to stand in any attitude he wanted to describe, and that it was his custom to place that creature near his easel; so that at the motion of his hand the bird would fix itself in the proper posture, and would continue in that particular position without the smallest perceptible alteration for several hours at a time. The landscapes which he introduces as the back grounds of his pictures, are adapted with peculiar judgment and skill, and admirably finished; they harmonize with his subject, and always increase the force and the beauty of his principal objects. His touch was very singular, in imitating the natural plumage of the fowls he painted; which not only produced a charming effect, but also may prove serviceable to an intelligent observer, to assist him in determining which are the genuine works of this master, and which are impositions. His pictures sell at a high price, and are much sought after. He died at Utrecht in 1695, aged 59.

HONDURAS, a province of North America in New Spain, lying on the North Sea, being about 370 miles in length, and 200 in breadth; it was discovered

Hone,
Honey.

ed by Christopher Columbus in the year 1502. The English have been possessed of the logwood country on the bay of Honduras a great while, and cut large quantities every year. The Mosquito native Americans live in the eastern parts; and being independent of the Spaniards, have entered into treaties with the English, and serve them in several capacities. This province is watered by several rivers, which enrich the country by their inundations; and it is very fertile in Indian corn. It is said there are some mines of gold and silver in this province. Valadolid is the capital town.

HONE, a fine kind of white stone, used for setting razors, pen-knives, and the like.

HONEY, a sweet vegetable juice, collected by the bees from the flowers of various plants, and deposited in the cells of the comb; from which it is extracted either by spontaneous percolation through a sieve in a warm place, the comb being separated and laid thereon, or by expression. That which runs spontaneously is purer than that which is expressed, a quantity of the wax and other matters being forced out along with it by the pressure. The best sort of honey is of a thick consistence, a whitish colour inclining to yellow, an agreeable smell, and pleasant taste: both the colour and flavour are said to differ in some degree, according to the plants which the bees collect it from. It is supposed that honey is merely the juice of the flower perspiring, and becoming inspissated thereon; and that the bee takes it up with its proboscis, and carries it to be deposited in its waxen cells, with which the young bees are to be fed in summer, and the old ones in winter: but it is certain, that honey can be procured by no other method of collecting this juice than by the bees. The honey wrought by the young bees, and that which is permitted to run from the comb without heat or pressure, is white and pure, and called *virgin's honey*. The honey of old bees, and that which is forced from the comb by heat or pressure, is yellow, from the wax. Honey produced where the air is clear and hot, is better than that where the air is variable and cold.—The honey of Narbonne in France, where rosemary abounds, is said to have a very manifest flavour of that plant, and to be imitable by adding to other honey an infusion of rosemary flowers.

Honey, considered as a medicine, is a very useful detergent and aperient, powerfully dissolving viscid juices, and promoting the expectoration of tough phlegm. In some particular constitutions it has an inconvenience of griping, or of proving purgative; which is said to be in some measure prevented by previously boiling the honey. This, however, with all constitutions, is by no means effectual; and the circumstance mentioned has had so much weight with the Edinburgh college, that they do not now employ it in any preparation, and have entirely rejected the *mella medicata*, substituting syrups in their place: but there can be no doubt that honey is very useful in giving form to different articles, although there be some individuals with whom it may disagree. In order, however, to obtain the good effects of the honey itself, it must be used to a considerable extent, and as an article of diet. The following remarkable instances of the good effects of honey in some asthmatic cases, given by Dr Monro in his Medical and Pharmaceutical

N^o 156.

Chemistry, deserve to be here inserted. “The late Dr John Hume, one of the commissioners of the sick and hurt of the royal navy, was for many years violently afflicted with the asthma. Having taken many medicines without receiving relief, he at last resolved to try the effects of honey, having long had a great opinion of its virtues as a pectoral. For two or three years he ate some ounces of it daily, and got entirely free of his asthma, and likewise of a gravelly complaint which he had long been afflicted with. About two years after he had recovered his health, when he was sitting one day in the office for the sick and hurt, a person labouring under a great difficulty of breathing, who looked as if he could not live many days, came to him, and asked him by what means he had been cured of his asthma? Dr Hume told him the particulars of his own case, and mentioned to him the means by which he had found relief. For two years after he heard nothing of this person, who was a stranger to him, and had seemed so bad that he did not imagine that he could have lived many days, and therefore had not even asked him who he was; but at the end of that period, a man seemingly in good health, and decently dressed, came to the sick and hurt office, and returned him thanks for his cure, which he assured him had been entirely brought about by the free use of honey.”

Honey-Dew, a sweet saccharine substance found on the leaves of certain trees, of which bees are very fond, by the husbandmen supposed to fall from the heavens like common dew. This opinion hath been refuted, and the true origin of this and other saccharine dews shown by the Abbe Boissier de Sauvages, in a memoir read before the Society of Sciences at Montpellier. “Chance (says the Abbe) afforded me an opportunity of seeing this juice in its primitive form on the leaves of the holm oak: these leaves were covered with thousands of small round globules or drops, which, without touching one another, seemed to point out the pore from whence each of them had proceeded. My taste informed me that they were as sweet as honey: the honey-dew on a neighbouring bramble did not resemble the former, the drops having run together; owing either to the moisture of the air which had diluted them, or to the heat which had expanded them. The dew was become more viscous, and lay in large drops, covering the leaves; in this form it is usually seen.

“The oak had at this time two sorts of leaves; the old, which were strong and firm; and the new, which were tender, and newly come forth. The honey-dew was found only on the old leaves; though these were covered by the new ones, and by that means sheltered from any moisture that could fall from above. I observed the same on the old leaves of the bramble, while the new leaves were quite free from it. Another proof that this dew proceeds from the leaves is, that other neighbouring trees not furnished with a juice of this kind had no moisture on them; and particularly the mulberry, which is a very particular circumstance, for this juice is a deadly poison to silk-worms. If this juice fell in the form of a dew, mist, or fog, it would wet all the leaves without distinction, and every part of the leaves, under as well as upper. Heat may have some share in its production: for

I

though

Honey.

though the common heat promotes only the transpiration of the more volatile and fluid juices, a sultry heat, especially if reflected by clouds, may so far dilate the vessel as to produce a more viscous juice, such as the honey-dew.

"The second kind of honey-dew, which is the chief resource of bees after the spring-flowers and dew by transpiration on leaves are past, owes its origin to a small insect called a *vine-fretter*; the excrement ejected with some force by this insect makes a part of the most delicate honey known in nature (see *APHIS*). These vine-fretters rest during several months on the barks of particular trees, and extract their food by piercing that bark, without hurting or deforming the tree. These insects also cause the leaves of some trees to curl up, and produce galls upon others. They settle on branches that are a year old. The juice, at first perhaps hard and crabbed, becomes, in the bowels of this insect, equal in sweetness to the honey obtained from the flowers and leaves of vegetables; excepting that the flowers may communicate some of their essential oil to the honey, and this may give it a peculiar flavour, as happened to myself by planting a hedge of rosemary near my bees at Sauvages: the honey has tasted of it ever since, that shrub continuing long in flower.

"I have observed two species of vine-fretters, which live unsheltered on the bark of young branches; a larger and a lesser. The lesser species is of the colour of the bark upon which it feeds, generally green. It is chiefly distinguished by two horns, or straight, immovable, fleshy substances, which rise perpendicularly from the lower sides of the belly, one on each side. This is the species which live on the young branches of bramble and elder. The larger species is double the size of the other; is of a blackish colour; and instead of the horns which distinguish the other, have in the same part of the skin a small button, black and shining like jet.

"The buzzing of bees in a tuft of holm-oak, made me suspect that something very interesting brought so many of them thither. I knew that it was not the season for expecting honey-dew, nor was it the place where it is usually found; and was surprised to find the tuft of leaves and branches covered with drops which the bees collected with a humming noise. The form of the drops drew my attention, and led me to the following discovery. Instead of being round like drops which had fallen, each formed a small longish oval. I soon perceived from whence they proceeded. The leaves covered with these drops of honey were situated beneath a swarm of the larger black vine-fretters; and on observing these insects, I perceived them from time to time raise their bellies, at the extremity of which there then appeared a small drop of an amber colour, which they instantly ejected from them to the distance of some inches. I found by tasting some of these drops which I had caught on my hand, that it had the same flavour with what had before fallen on the leaves. I afterwards saw the smaller species of vine-fretters eject their drops in the same manner. This ejection is so far from being a matter of indifference to these insects themselves, that it seems to have been wisely instituted to procure cleanliness in each individual, as well as to preserve the whole swarm

VOL. VIII. Part II.

from destruction; for pressing as they do one upon another, they would otherwise soon be glued together, and rendered incapable of stirring. The drops thus spurted out fall upon the ground, if not intercepted by leaves or branches; and the spots they make on stones remain some time, unless washed off by rain. This is the only honey-dew that falls; and this never falls from a greater height than a branch where these insects can cluster.

"It is now easy to account for a phenomenon which formerly puzzled me greatly. Walking under a lime-tree in the king's garden at Paris, I felt my hand wetted with little drops, which I at first took for small rain. The tree indeed should have sheltered me from the rain, but I escaped it by going from under the tree. A seat placed near the tree shone with these drops. And being then unacquainted with any thing of this kind, except the honey-dew found on the leaves of some particular trees, I was at a loss to conceive how so glutinous a substance could fall from the leaves in such small drops: for I knew that rain could not overcome its natural attraction to the leaves till it became pretty large drops; but I have since found, that the lime-tree is very subject to these vine-fretters.

"Bees are not the only insects that feast upon this honey; ants are equally fond of it. Led into this opinion by what naturalists have said, I at first believed that the horns in the lesser species of these vine-fretters had in their extremity a liquor which the ants went in search of: but I soon discovered that what drew the ants after them came from elsewhere, both in the larger and lesser species, and that no liquor is discharged by the horns. There are two species of ants which search for these insects. The large black ants follow those which live on the oaks and chestnut; the lesser ants attend those on the elder. But as the ants are not, like the bees, provided with the means of sucking up fluids; they place themselves near the vine-fretters, in order to seize the drop the moment they see it appear upon the anus; and as the drop remains some time on the small vine-fretters before they can cast it off, the ants have leisure to catch it, and thereby prevent the bees from having any share: but the vine-fretters of the oak and chestnut being stronger, and perhaps more plentifully supplied with juice, dart the drop instantly, so that the larger ants get very little of it.

"The vine-fretters finding the greatest plenty of juice in trees about the middle of summer, afford also at that time the greatest quantity of honey; and this lessens as the season advances, so that in the autumn the bees prefer it to the flowers then in season. Though these insects pierce the tree to the sap in a thousand places, yet the trees do not seem to suffer at all from them, nor do the leaves lose the least of their verdure. The husbandman therefore acts injudiciously when he destroys them."

HONEY-GUIDE, a curious species of cuckoo. See *CUCULUS*.

and trade in bone-lace. It is seated on the river Seine, in E. Long. o. 8. N. Lat. 17. 49.

HONI SOIT QUI MAL Y PENSE, q. d. "Evil to him that thinks evil;" the motto of the most noble order of the knights of the Garter. See GARTER.

HONITON, a very pleasant market and borough-town in Devonshire, situated 156 miles W. of London, and 16 east of Exeter. It consists of about 400 houses; and has one church on a hill full half a mile from the town, and a chapel and free grammar-school in the town. It is well paved and lighted, and lakes of water run through it. This place has suffered by fires greatly in 1747 and 1765. The market is on Saturday, and one fair in July: its manufactures are serge, and rich bone-lace and edgings. It was a chartered corporation by James II. but reverted to its old constitution on the revolution, and is now governed by a portreeve who is chosen annually. It first returned members the 28th Edw. I.

HONORIACI, in antiquity, an order of soldiery under the eastern empire, who introduced the Goths, Vandals, Alani, Suevi, &c. into Spain. Didymus and Verinianus, two brothers, had, with great vigilance and valour, defended the passages of the Pyreneans against the Barbarians for some time, at their own expence; but being at length killed, the emperor Constantius appointed the *honoriaci* to defend those passages, who, not contented to lay them open to all the nations of the north then ravaging the Gauls, joined themselves to them.

HONOUR, a testimony of esteem or submission, expressed by words, actions, and an exterior behaviour, by which we make known the veneration and respect we entertain for any one on account of his dignity or merit. The word *honour* is also used in general for the esteem due to virtue, glory, and reputation. It is also used for *virtue* and *probity* themselves, and for an exactness in performing whatever we have promised; and in this last sense we use the term, *a man of honour*. But *honour* is more particularly applied to two different kinds of virtue; bravery in men, and chastity in women.—Virtue and Honour were deified among the ancient Greeks and Romans, and had a joint temple consecrated to them at Rome: but afterwards each of them had separate temples, which were so placed, that no one could enter the temple of Honour without passing through that of Virtue; by which the Romans were continually put in mind, that virtue is the only direct path to true glory. Plutarch tells us, that the Romans, contrary to their usual custom, sacrificed to Honour uncovered; perhaps to denote, that wherever honour is, it wants no covering, but shows itself openly to the world.

The Spanish historians relate a memorable instance of honour and regard to truth. A Spanish cavalier in a sudden quarrel slew a Moorish gentleman, and fled. His pursuers soon lost sight of him, for he had unperceived thrown himself over a garden wall. The owner, a Moor, happening to be in his garden, was addressed by the Spaniard on his knees, who acquainted him with his case, and implored concealment. "Eat this," said the Moor (giving him half a peach), "you now know that you may confide in my protection." He then locked him up in his garden apartment, telling him as soon as it was night he would provide for his

escape to a place of greater safety. The Moor then went into his house, where he had but just seated himself, when a great crowd, with loud lamentations, came to his gate, bringing the corpse of his son, who had just been killed by a Spaniard. When the first shock of surprise was a little over, he learnt from the description given, that the fatal deed was done by the very person then in his power. He mentioned this to no one; but as soon as it was dark retired to his garden, as if to grieve alone, giving orders that none should follow him. Then accosting the Spaniard, he said, "Christian, the person you have killed is my son, his body is now in my house. You ought to suffer; but you have eaten with me, and I have given you my faith, which must not be broken." He then led the astonished Spaniard to his stables, mounted him on one of his fleetest horses, and said, "Fly far while the night can cover you; you will be safe in the morning. You are indeed guilty of my son's blood: but God is just and good; and I thank him I am innocent of yours, and that my faith given is preserved."

This point of honour is most religiously observed by the Arabs and Saracens, from whom it was adopted by the Moors of Africa, and by them was brought into Spain. The following instance of Spanish honour may still dwell in the memory of many living, and deserves to be handed down to the latest posterity. In the year 1746, when we were in hot war with Spain, the Elizabeth of London, captain William Edwards, coming through the Gulph from Jamaica, richly laden, met with a most violent storm, in which the ship sprung a leak, that obliged them, for the saving of their lives, to run into the Havannah, a Spanish port. The captain went on shore, and directly waited on the governor, told the occasion of his putting in, and that he surrendered the ship as a prize, and himself and his men as prisoners of war, only requesting good quarter. "No, Sir," replied the Spanish governor, "if we had taken you in fair war at sea, or approaching our coast with hostile intentions, your ship would then have been a prize, and your people prisoners; but when, distressed by a tempest, you come into our ports for the safety of your lives, we, the enemies, being men, are bound as such by the laws of humanity to afford relief to distressed men who ask it of us. We cannot even against our enemies take advantage of an act of God. You have leave therefore to unload your ship, if that be necessary, to stop the leak; you may reside here, and traffic so far as shall be necessary to pay the charges; you may then depart, and I will give you a pass to be in force till you are beyond Bermuda: if after that you are taken, you will then be a lawful prize; but now you are only a stranger, and have a stranger's right to safety and protection." The ship accordingly departed, and arrived safe in London.

A remarkable instance of the like honour is recorded of a poor unenlightened African negro, in Captain Snelgrave's account of his voyage to Guinea. A New England sloop, trading there in 1752, left a second mate, William Murray, sick on shore, and sailed without him. Murray was at the house of a black named Cudjoe, with whom he had contracted an acquaintance during their trade. He recovered; and the sloop being gone, he continued with his black friend till some other opportunity should offer of his getting home.

Honour

In

Honour. In the mean time a Dutch ship came into the road, and some of the blacks coming on board her, were treacherously seized and carried off as their slaves. The relations and friends, transported with sudden rage, ran into the house of Cudjoe, to take revenge by killing Murray. Cudjoe stooped them at the door, and demanded what they wanted. "The white men," said they, "have carried away our brothers and sons, and we will kill all white men. Give us the white man you have in your house, for we will kill him." "Nay," said Cudjoe, "the white men that carried away your relations are bad men, kill them when you can take them; but this white man is a good man, and you must not kill him."—"But he is a white man," they cried; "and the white men are all bad men, we will kill them all." "Nay," says he, "you must not kill a man that has done no harm, only for being white. This man is my friend, my house is his post, I am his soldier, and must fight for him; you must kill me before you can kill him. What good man will ever come again under my roof, if I let my floor be stained with a good man's blood?" The negroes seeing his resolution, and being convinced by his discourse that they were wrong, went away ashamed. In a few days Murray ventured abroad again with his friend Cudjoe, when several of them took him by the hand, and told him, "They were glad they had not killed him; for as he was a good (meaning innocent) man, their God would have been very angry, and would have spoiled their fishing."

HONOUR, in the *beau monde*, has a meaning materially different from the above, and which it is easier to illustrate than define. It is, however, subject to a system of rules, called the *law of honour*, constructed by people of fashion, calculated to facilitate their intercourse with one another, and for no other purpose. Consequently, nothing is considered as inconsistent with honour, but what tends to incommode this intercourse. Hence, as Archdeacon Paley states the matter, profaneness, neglect of public worship or private devotion, cruelty to servants, rigorous treatment of tenants or other dependants, want of charity to the poor, injuries done to tradesmen by insolvency or delay of payment, with numberless examples of the same kind, are accounted no breaches of honour; because a man is not a less agreeable companion for these vices, nor the worse to deal with in those concerns which are usually transacted between one gentleman and another.—Again, the *law of honour* being constituted by men occupied in the pursuit of pleasure, and for the mutual convenience of such men, will be found, as might be expected from the character and design of the law-makers, to be, in most instances, favourable to the licentious indulgence of the natural passions. Thus it allows of fornication, adultery, drunkenness, prodigality, duelling, and revenge in the extreme; and lays no stress upon the virtues opposite to these.

HONOUR or Rank—The degrees of honour which are observed in Britain may be comprehended under these two heads, viz. *nobiles majores*, and *nobiles minores*. Those included under the first rank are, archbishops, dukes, marquises, earls, viscounts, bishops, and barons; which are all distinguished by the respective ornaments of their

escutcheons: and those of the last are baronets, knights, esquires, and gentlemen. There are some authors who will have baronets to be the last under the first rank; and their reason is, because their honour is hereditary, and by patent, as that of the nobility. See **COMMONALTY and NOBILITY**.

HONOURS of War, in a siege, is, when a governor, having made a long and vigorous defence, is at last obliged to surrender the place to the enemy for want of men and provisions, and makes it one of his principal articles to march out with the *honours of war*; that is, with shouldered arms, drums beating, colours flying, and all their baggage, &c.

Military HONOURS. All armies salute crowned heads in the most respectful manner, drums beating a march, colours and standards dropping, and officers saluting. Their guards pay no compliment, except to the princes of the blood; and even that by courtesy, in the absence of the crowned head.

To the commander in chief the whole line turns out without arms, and the camp-guards beat a march, and salute. To generals of horse and foot, they beat a march, and salute. Lieutenant-generals of ditto, three ruffs, and salute. Major-generals of ditto, two ruffs, and salute. Brigadiers of ditto, rested arms, one ruff, and salute. Colonels of ditto, rested arms, and no beating. Centinels rest their arms to all field-officers, and shoulder to every officer. All governors, that are not general officers, shall, in all places where they are governors, have one ruff, with rested arms; but for those who have no commission as governors, no drum shall beat. Lieutenant-governors shall have the main-guard turned out to them with shouldered arms.

Prussian HONOURS of War, chiefly imitated by most powers in Europe, are,

To the king, all guards beat the march, and all officers salute. Field-marsbals received with the march, and saluted in the king's absence. General of horse or foot, four ruffs; but if he commands in chief, a march and salute. Lieutenant-generals of horse or foot, commanding or not, guards beat three ruffs. Major-generals of horse and foot, two ruffs. Officers, when their guards are under arms, and a general makes a signal, must rest to him, but not beat; when not got under arms, and a signal made, only stand by their arms. Village-guards go under arms only to the king, field-marsbals, generals of horse and foot, and to the general of the day. Generals guards go under arms only to the king, field-marsbals, and the general over whom they mount. Commanding officers of regiments and battalions, their own quarter and rear guards to turn out; but not to other field-officers, unless they are of the day. Generals in foreign service, the same.

HONOURS paid by Centinels. Field-marsbals; two centinels with ordered fire-locks, at their tent or quarters. Generals of horse or foot; two centinels, one, with his firelock shouldered, the other ordered. Lieutenant-generals; one, with firelock ordered. Major-generals; one, with firelock shouldered.

The first battalion of guards go under arms to the king only; not to stand by, nor draw up in the rear of their arms to any other; nor to give centinels to foreigners. Second and third battalions draw up behind their arms to the princes, and to field-marsbals;

Honour.

but when on grenadier-guards or out-posts, they turn out, as other guards do, to the officers of the day. They give one centinel with shouldered arms to the princes of the blood, and to field-m Marshals when they lie alone in garrison.

Court of Honour. See *Court of Chivalry*.

Fountain of Honour. The king is so styled, as being the source of honours, dignities, &c. See *PREROGATIVE*.

It is impossible that government can be maintained without a due subordination of rank; that the people may know and distinguish such as are set over them, in order to yield them their due respect and obedience; and also that the officers themselves, being encouraged by emulation and the hopes of superiority, may the better discharge their functions: and the law supposes, that no one can be so good a judge of their several merits and services as the king himself who employs them. It has therefore entrusted him with the sole power of conferring dignities and honours, in confidence that he will bestow them upon none but such as deserve them. And therefore all degrees of nobility, of knighthood, and other titles, are received by immediate grant from the crown: either expressed in writing, by writs or letters patent, as in the creation of peers and baronets; or by corporeal investiture, as in the creation of a simple knight.

From the same principle also arises the prerogative of erecting and disposing of offices: for honours and offices are in their nature convertible and synonymous. All offices under the crown carry in the eye of the law an honour along with them; because they imply a superiority of parts and abilities, being supposed to be always filled with those that are most able to execute them. And, on the other hand, all honours in their original had duties or offices annexed to them: an earl, *comes*, was the conservator or governor of a county; and a knight, *miles*, was bound to attend the king in his wars. For the same reason therefore that honours are in the disposal of the king, offices ought to be so likewise; and as the king may create new titles, so may he create new offices: but with this restriction, that he cannot create new offices with new fees annexed to them, nor annex new fees to old offices; for this would be a tax upon the subject, which cannot be imposed but by act of parliament. Wherefore, in 13 Hen. IV. a new office being created by the king's letters patent for measuring cloths, with a new fee for the same, the letters patent were, on account of the new fee, revoked and declared void in parliament.

Upon the same or a like reason, the king has also the prerogative of conferring privileges upon private persons. Such as granting place or precedence to any of his subjects; as shall seem good to his royal wisdom: or such as converting aliens, or persons born out of the king's dominions, into denizens; whereby some very considerable privileges of natural-born subjects are conferred upon them. Such also is the prerogative of erecting corporations; whereby a number of private persons are united and knit together, and enjoy many liberties, powers, and immunities in their politic capacity, which they were utterly incapable of in their natural.

Maids of Honour, are young ladies in the queen's household, whose office is to attend the queen when she goes abroad, &c. In England they are six in number, and their salary 300 l. *per annum* each.

HONOUR is particularly applied in our customs to the more noble kind of feignories or lordships, whereof other inferior lordships or manors hold or depend. As a manor consists of several tenements, services, customs, &c. so an honour contains divers manors, knights-fees, &c. It was also formerly called *beneficium* or *royal fee*, being always held of the king *in capite*.

HONOUR-Point, in heraldry, is that next above the centre of the escutcheon, dividing the upper part into two equal portions.

HONOURABLE, a title conferred on the younger sons of earls, the sons of viscounts and barons; as also on such persons as have the king's commission, and upon those who enjoy places of trust and honour.

HONOURARY, something done or conferred upon any one, to do him honour. See the article *HONOUR*.

Honourary is sometimes understood of a person who bears or possesses some post or title, only for the name's sake, without doing any thing of the functions belonging to it, or receiving any advantage from it: thus we say honourary counsellors, honourary fellows, &c.

Honourary is also used for a lawyer's fee, or a salary given to public professors in any art or science.

HOOD (Robin), a famous outlaw and deer-stealer, who chiefly harboured in Sherwood forest in Nottinghamshire. He was a man of family, which by his pedigree appears to have had some title to the earldom of Huntingdom; and played his pranks about the latter end of the 12th century. He was famous for archery, and for his treatment of all travellers who came in his way; levying contributions on the rich, and relieving the poor. Falling sick at last, and requiring to be blooded, he is said to have been betrayed and bled to death. He died in 1247; and was buried at Kirkstree in Yorkshire, then a Benedictine monastery, where his gravestone is still shown.

HOOD. See *CHAPERON* and *COWL*.

Hood, in falconry, is a piece of leather, wherewith the head of a hawk, falcon, or the like, is covered.

Hood Island, one of the *MARQUESAS Islands*, in the South Sea. It was discovered in April 1774 by captain Cook, who gave it that name from the person who first saw the land. It is the most northerly of the cluster, and lies in S. Lat. 9. 26. W. Long. 139. 13.

HOOF, the horny substance that covers the feet of divers animals, as oxen, horses, &c.

Hoof-bound, in farriery. See there, § xlii.

HOOF (Peter Cornelius Van), an eminent historian and poet, born at Amsterdam in 1581. He was lord of Muyden, judge of Goyland, and knight of the order of St Michael. He died at the Hague in 1647. He wrote, 1. An excellent history of the Netherlands, from the abdication of Charles V. to the year 1588. 2. Several Comedies, and other works. By these he acquired such reputation, that the Flemings considered him as the Homer and Tacitus of the Netherlands.

HOOGUES.

Honour

Hoof.

Hooguest-
ratten
||
Hooke.

HOOGUESTRATTEN, a town of the Netherlands, in Dutch Brabant, and capital of a county of the same name. E. Long. 4. 41. N. Lat. 51. 25.

HOOK, in angling, &c. See *FISHING-hook*.

HOOKS, in building, &c. are of various sorts; some of iron and others of brass, viz. 1. Armour-hooks, which are generally of brass, and are to lay up arms upon, as guns, muskets, half-pikes, pikes, javelins, &c. 2. Casement-hooks. 3. Chimney-hooks, which are made both of brass and iron, and of different fashions: their use is to set the tongs and fire-shovel against. 4. Curtain-hooks. 5. Hooks for doors, gates, &c. 6. Double line-hooks, large and small. 7. Single line-hooks, large and small. 8. Tenter-hooks of various sorts. See *TENTER*.

HOOKS of a ship, are all those forked timbers which are placed directly upon the keel, as well in her run as in her rake.

Can-HOOKS, those which being made fast to the end of a rope with a noose (like that which brewers use to sling or carry their barrels on), are made use of for slings.

Foot-HOOKS, in a ship, the same with futtocks.

Loof-HOOKS, a tackle with two hooks; one to hitch into a cringle of the main or fore-sail, in the bolt-rope at the leech of the sail by the clew; and the other is to hitch into a strap, which is spliced to the chess-tree.

Their use is to pull down the sail, and succour the tackles in a large sail and stiff gale, that all the stress may not bear upon the tack. It is also used when the tack is to be seized more secure, and to take off or put on a bonnet or drabler.

Hook Pins, in architecture, are taper iron pins, only with a hook-head, to pin the frame of a roof or floor together.

HOOKAH, among the Arabs and other nations of the East, is a pipe of a singular and complicated construction, through which tobacco is smoked: out of a small vessel of a globular form, and nearly full of water, issue two tubes, one perpendicularly, on which is placed the tobacco; the other obliquely from the side of the vessel, and to that the person who smokes applies his mouth; the smoke by this means being drawn through water, is cooled in its passage and rendered more grateful: one takes a whiff, draws up a large quantity of smoke, puffs it out of his nose and mouth in an immense cloud, and passes the hookah to his neighbour; and thus it goes round the whole circle.—The hookah is known and used throughout the east; but in those parts of it where the refinements of life prevail greatly, every one has his hookah sacred to himself; and it is frequently an implement of a very costly nature, being of silver, and set with precious stones: in the better kind, that tube which is applied to the mouth is very long and pliant; and for that reason is termed the snake: people who use it in a luxurious manner, fill the vessel through which the smoke is drawn with rose water, and it thereby receives some of the fragrant quality of that fluid.

HOOKE (Robert), a very eminent English mathematician and philosopher, was the son of Mr John Hooke minister of Freshwater in the Isle of Wight, where he was born in 1635. He very early discovered a genius for mechanics, by making curious toys with great art and dexterity. He was educated under Dr

Busby in Westminster school; where he not only acquired a competent share of Greek and Latin, together with an insight into Hebrew and some other Oriental languages, but also made himself master of a good part of Euclid's elements. About the year 1653 he went to Christ-church in Oxford, and in 1655 was introduced to the Philosophical Society there; where, discovering his mechanic genius, he was first employed to assist Dr Willis in his operations in chemistry, and afterwards recommended to the honourable Robert Boyle, Esq; whom he served several years in the same capacity. He was also instructed in astronomy about this time by Dr Seth Ward, Savilian professor of that science; and from henceforward distinguished himself by many noble inventions and improvements of the mechanic kind. He invented several astronomical instruments, for making observations both at sea and land; and was particularly serviceable to Mr Boyle in completing the invention of the air-pump. Sir John Cutler having founded a mechanic school in 1664, he settled an annual stipend on Mr Hooke for life, intrusting the president, council, and fellows, of the Royal Society to direct him with respect to the number and subject of his lectures; and on the 11th of January 1664-5, he was elected by that society curator of experiments for life, with an additional salary. In 1666 he produced to the Royal Society a model for rebuilding the city of London destroyed by fire, with which the society was well pleased; and the lord mayor and aldermen preferred it to that of the city surveyor, though it happened not to be carried into execution. It is said, by one part of this model of Mr Hooke's, it was designed to have all the chief streets, as from Leaden-hall to Newgate, and the like, to lie in exact straight lines, and all the other cross-streets turning out of them at right angles, with all the churches, public buildings, markets, &c. in proper and convenient places. The rebuilding of the city according to the act of parliament requiring an able person to set out the ground to the proprietors, Mr Hooke was appointed one of the surveyors; in which employment he got most part of his estate, as appeared pretty evident from a large iron chest of money found after his death, locked down with a key in it, and a date of the time, which showed it to have been so shut up above 30 years.—Mr Oldenburgh, secretary to the Royal Society, dying in 1677, Mr Hooke was appointed to supply his place, and began to take minutes at the meeting in October, but did not publish the Transactions. In the beginning of the year 1687, his brother's daughter, Mrs Grace Hooke, who had lived with him several years, died; and he was so affected with grief at her death, that he hardly ever recovered it, but was observed from that time to become less active, more melancholy, and, if that could be, more cynical than ever. At the same time, a chancery suit in which he was concerned with Sir John Cutler, on account of his salary for reading the Cutlerian lectures, made him very uneasy, and increased his disorder. In 1691, he was employed in forming the plan of the hospital near Hoxton, founded by Robert Ask alderman of London, who appointed archbishop Tillotson one of his executors; and in December the same year, Hooke was created doctor of physic, by a warrant from that

Hooke.

Hooker. prelate. In July 1696, the chancery suit with Sir John Cutler was determined in his favour, to his inexpressible satisfaction. His joy on that occasion was found in his diary thus expressed; DOMSHLGISSA: that is, *Deo, Optimo, Maximo, sit honor, laus, gloria, in secula seculorum, Amen.* "I was born on this day of July 1635, and God hath given me a new birth: may I never forget his mercies to me! while he gives me breath may I praise him!"—In the same year 1696, an order was granted to him for repeating most of his experiments at the expence of the Royal Society, upon a promise of his finishing the accounts, observations, and deductions from them, and of perfecting the description of all the instruments contrived by him; but his increasing illness and general decay rendered him unable to perform it. He continued some years in this wasting condition; and thus languishing till he was quite emaciated, he died March 3d, 1702, at his lodgings in Gresham college, and was buried in St Helen's church, Bishopsgate street; his corpse being attended by all the members of the Royal Society then in London.—As to Mr Hooke's character, it is not in all respects one of the most amiable. He made but a despicable figure as to his person, being short of stature, very crooked, pale, lean, and of a meagre aspect, with dark brown hair, very long, and hanging over his face uncut and lank. Suitable to his person, his temper was penurious, melancholy, mistrustful: and, though possessed of great philosophical knowledge, he had so much ambition, that he would be thought the only man who could invent or discover; and thus frequently laid claim to the inventions and discoveries of others, while he boasted of many of his own which he never communicated. In the religious part of his character he was so far exemplary, that he always expressed a great veneration for the Deity; and seldom received any remarkable benefit in life, or made any considerable discovery in nature, or invented any useful contrivance, or found out any difficult problem, without setting down his acknowledgment to God, as many places in his diary plainly show. He frequently studied the sacred writings in the original; for he was acquainted with the ancient languages, as well as with all parts of the mathematics.—He wrote, 1. *Lectures Cutlerianæ*, 2. *Micrographia*, or Descriptions of minute bodies made by magnifying glasses. 3. A description of helioscopes. 4. A description of some mechanical improvements of lamps and water-poises, quarto. 5. Philosophical collections. After his death were published, 6. Posthumous work collected from his papers by Richard Waller secretary to the Royal Society.

HOOKE (Nathaniel), author of an esteemed Roman history and other performances. Of this learned gentleman the earliest particulars to be met with are furnished by himself, in the following modest but manly address to the Earl of Oxford, dated Oct. 7. 1722: "My Lord, the first time I had the honour to wait upon your lordship since your coming to London, your lordship had the goodness to ask me, what way of life I was then engaged in; a certain *mauvaise honte* hindered me at that time from giving a direct answer. The truth is, my lord, I cannot be said at present to be in any form of life, but rather to live extempore. The late epidemical distemper seized me,

I endeavoured to be rich, imagined for a while that I was, and am in some measure happy to find myself at this instant but just worth nothing. If your lordship, or any of your numerous friends, have need of a servant, with the bare qualifications of being able to read and write, and to be honest, I shall gladly undertake any employments your lordship shall not think me unworthy of. I have been taught, my lord, that neither a man's natural pride, nor his self-love, is an equal judge of what is fit for him; and I shall endeavour to remember, that it is not the short part we act, but the manner of our performance, which gains or loses us the applause of Him who is finally to decide of all human actions. My lord. I am just now employed in translating from the French, a History of the Life of the late archbishop of Cambray; and I was thinking to beg the honour of your lordship's name to protect a work which will have so much need of it. The original is not yet published. 'Tis written by the author of the 'Discourse upon Epic Poetry,' in the new edition of *Telemaque*. As there are some passages in the book of a particular nature, I dare not solicit your lordship to grant me the favour I have mentioned, till you first have perused it. The whole is short, and pretty fairly transcribed. If your lordship could find a spare hour to look it over, I would wait upon your lordship with it, as it may possibly be no unpleasing entertainment. I should humbly ask your lordship's pardon for so long an address in a season of so much business. But when should I be able to find a time in which your lordship's goodness is not employed? I am, with perfect respect and duty, my lord, your lordship's most obliged, most faithful, and most obedient humble servant, NATHANIEL HOOKE." The translation here spoken of was afterwards printed in 12mo, 1723. From this period till his death, Mr Hooke enjoyed the confidence and patronage of men not less distinguished by virtue than by titles. In 17... he published a translation of Ramsay's *Travels of Cyrus*, in 4to; in 1733 he revised a translation of "The History of the Conquest of Mexico by the Spaniards, by Thomas Townsend, Esq;" printed in 2 vols 8vo; and in the same year he published, in 4to, the first volume of "The Roman History, from the building of Rome to the ruin of the Commonwealth; illustrated with maps and other plates." In the dedication to this volume, Mr Hooke took the opportunity of "publicly testifying his just esteem for a worthy friend, to whom he had been long and much obliged," by telling Mr Pope, that the displaying of his name at the head of those sheets was "like the hanging out a splendid sign, to catch the traveller's eye, and entice him to make trial of the entertainment the place affords. But," he proceeds, "when I can write under my sign, that Mr Pope has been here, and was content, who will question the goodness of the house?" The volume is introduced by "Remarks on the History of the Seven Roman Kings, occasioned by Sir Isaac Newton's objections to the supposed 244 years duration of the royal state of Rome." His nervous pen was next employed in digesting "An Account of the conduct of the Dowager-duchess of Marlborough, from her first coming to Court to the year 1710, in a Letter from herself to Lord —. in 1742." 8vo. His reward on this

Nichols's
Anecdotes of
Bouyer,
&c.

Hooker. this occasion was considerable; and the reputation he acquired by the performance much greater. The circumstances of this transaction are thus related by Dr Maty, in his *Memoires of Lord Chesterfield*, vol. i. p. 116. "The relict of the great duke of Marlborough, being desirous of submitting to posterity her political conduct, as well as her lord's, applied to the earl of Chesterfield for a proper person to receive her information, and put the memoirs of her life into a proper dress. Mr Hooke was recommended by him for that purpose. He accordingly waited upon the duchess, while she was still in bed, oppressed by the infirmities of age. But, knowing who he was, she immediately got herself lifted up, and continued speaking during six hours. She delivered to him, without any notes, her account, in the most lively as well as the most connected manner. As she was not tired herself, she would have continued longer the business of this first sitting, had not she perceived that Mr Hooke was quite exhausted, and wanted refreshment as well as rest. So eager was she for the completion of the work, that she insisted upon Mr Hooke's not leaving her house till he had finished it. This was done in a short time; and her Grace was so well pleased with the performance, that she complimented the author with a present of 5000*l.* a sum which far exceeded his expectations. As soon as he was free, and permitted to quit the house of his benefactress, he hastened to the earl, to thank him for his favour, and communicated to him his good fortune. The perturbation of mind he was under, occasioned by the strong sense of his obligation, plainly appeared in his stammering out his acknowledgments: and he, who had succeeded so well as the interpreter of her Grace's sentiments, could scarcely utter his own." The second volume of his Roman history appeared in 1745; when Mr Hooke embraced the fair occasion of congratulating his worthy friend the earl of Marchmont, on "that true glory, the consenting praise of the honest and the wise," which his lordship had so early acquired. To the second volume Mr Hooke added "The Capitoline Marbles, or Consular Calendars, an ancient Monument accidentally discovered at Rome in the year 1545, during the Pontificate of Paul III." In 1758 Mr Hooke published "Observations on, I. The Answer of M. l'Abbe de Vertot to the late earl of Stanhope's Inquiry concerning the Senate of ancient Rome: dated December, 1719. II. A Dissertation upon the Constitution of the Roman Senate, by a Gentleman: published in 1743. III. A Treatise on the Roman Senate, by Dr Conyers Middleton: published in 1747. IV. An Essay on the Roman Senate, by Dr Thomas Chapman: published in 1750;" which he with great propriety inscribed to Mr Speaker Onslow. The third volume of Mr Hooke's Roman History, to the end of the Gallic war, was printed under his inspection before his last illness; but did not appear till after his death, which happened in 1764. The fourth and last volume was published in 1771. Mr Hooke left two sons; of whom one is a divine of the church of England; the other, a doctor of the Sorbonne, and professor of astronomy in that illustrious seminary.

HOOKE (John), *alias* VOWELL, was born in Exeter, about the year 1524, the second son of Robert Hooker, who in 1529 was mayor of that city.

He was instructed in grammar learning by Dr Moreman, vicar of Menhinit in Cornwall, and thence removed to Oxford; but to what college is uncertain. Having left the university, he travelled to Germany, and resided some time at Cologne, where he kept exercises in law, and probably graduated. Thence he went to Strasburg, where he studied divinity under the famous Peter Martyr. He now returned to England, and soon after visited France, intending to proceed to Spain and Italy; but was prevented by a declaration of war. Returning therefore again to England, he fixed his residence in his native city, where, having married, he was in 1554 elected chamberlain, being the first person who held that office, and in 1571 represented his fellow-citizens in parliament. He died in the year 1601, and was buried in the cathedral church at Exeter. He wrote, among other works, 1. Order and usage of keeping of parliaments in Ireland. 2. The events of comets or blazing stars, made upon the sight of the comet Pagonia, which appeared in November and December 1577. 3. An addition to the chronicles of Ireland from 1546 to 1568; in the second volume of Holinshed's chronicle. 4. A description of the city of Exeter, and of the fondrie assaults given to the same; Holinsh. chron. vol. iii. 5. A book of ensigns. 6. Translation of the history of the conquest of Ireland from the Latin of Giraldus Cambrensis; in Holinsh. chron. vol. ii. 7. *Synopsis chorographica*, or an historical record of the province of Devon; never printed.

HOOKE (Richard), a learned divine, was born at Heavy-tree, near Exeter, in the year 1553. Some of his ancestors were mayors of that city, and he was nephew to John HOOKER the historian. By this uncle he was first supported at the university of Oxford, with the addition of a small pension from Dr Jewel, bishop of Salisbury, who in 1561 got him admitted one of the clerks of Corpus-Christi college. In 1573 he was elected scholar. In 1577 he took the degree of master of arts, and was admitted fellow the same year. In July 1579, he was appointed deputy professor of the Hebrew language. In October, in the same year, he was for some trivial misdemeanor expelled the college, but was immediately restored. In 1581 he took orders; and, being appointed to preach at St Paul's cross, he came to London, where he was unfortunately drawn into a marriage with Joan Churchman, the termagant daughter of his hostess. Having thus lost his fellowship, he continued in the utmost distress till the year 1584, when he was presented by John Cheney, Esq; to the rectory of Drayton-Beaucham in Buckinghamshire. In this retirement he was visited by Mr Edwin Sandys, and Mr George Cranmer, his former pupils. They found him, with a Horace in his hand, tending some sheep in the common field, his servant having been ordered home by his sweet Xantippe. They attended him to his house; but were soon deprived of his company by an order from his wife Joan, for him to come and rock the cradle. Mr Sandys's representation to his father, of his tutor's situation, procured him the mastership of the Temple. In this situation he met with considerable molestation from one Travers, lecturer of the Temple, and a bigoted Puritan, who in the afternoon endeavoured to confute the doctrine delivered in the morning. From this disagreeable situation

Hooker

tion

Hooker,

Hooper.

tion he solicited archbishop Whitgift to remove him to some country retirement, where he might prosecute his studies in tranquillity. Accordingly, in 1591, he obtained the rectory of Boscomb in Wiltshire, together with a prebend in the church of Salisbury, of which he was also made sub-dean. In 1594 he was presented to the rectory of Bishopsbourne in Kent, where he died in the year 1600. He was buried in his own parish-church, where a monument was erected to his memory by William Cooper, Esq. He was a meek, pious, and learned divine. He wrote, 1. Ecclesiastical politie, in eight books, fol. 2. A discourse of justification, &c. with two other sermons, Oxford 1612, 4to. Also several other sermons printed with the Ecclesiastical Politie.

HOOKER, in naval architecture, a vessel much used by the Dutch, built like a pink, but rigged and masted like a hoy.—Hookers will lie nearer a wind than vessels with cross-sails can do. They are from 50 to 200 tons burden, and with a few hands will sail to the East Indies.

HOOP, a piece of pliant wood, or iron, bent into a circular form, commonly used for securing casks, &c.

Driving a Hoop, a boyish exercise, of good effect in rendering the limbs pliable, and for strengthening the nerves.

HOOPER (John), bishop of Worcester, and a martyr in the Protestant cause, was born in Somersetshire, and educated at Oxford, probably in Merton-college. In 1518 he took the degree of bachelor of arts, and afterwards became a Cistercian monk; but at length, disliking his fraternity, he returned to Oxford, and there became infected with Lutheranism. In 1539 he was made chaplain and house-steward to Sir John Arundel, who afterwards suffered with the protector in the reign of Edward VI. But *that very catholic knight*, as Wood calls him, discovering his chaplain to be a heretic, Hooper was obliged to leave the kingdom. After continuing some time in France, he returned to England, and lived with a gentleman called *Seintlow*: but being again discovered, he escaped in the habit of a sailor to Ireland; thence embarked for the continent, and fixed his abode in Switzerland.—When king Edward came to the crown, Mr Hooper returned once more to his native country. In 1550, by his old patron Sir John Arundel's interest with the earl of Warwick, he was consecrated bishop of Gloucester; and in 1552 was nominated to the see of Worcester, which he held *in commendam* with the former. But queen Mary had scarce ascended the throne, before his lordship was imprisoned, tried, and, not choosing to recant, condemned to the flames. He suffered this terrible death at Gloucester, on the 9th of February 1554, being then near 60 years of age. He was an avowed enemy to the church of Rome, and not perfectly reconciled to what he thought remnants of Popery in the church of England. In the former reign he had been one of Bonner's accusers, which sufficiently accounts for his being one of queen Mary's first sacrifices to the holy see. He was a person of good parts and learning, as may be found in Fox's Book of Martyrs.

HOOPER (George), a very learned writer, bishop of Bath and Wells, was well skilled in mathematics, and N^o 157.

in the eastern learning and languages. He sat in those fees above 24 years, often refused a seat in the privy council, and could not be prevailed upon to accept of the bishopric of London on the death of bishop Compton. He wrote, 1. The church of England free from the imputation of Popery. 2. A discourse concerning Lent. 3. New danger of Presbytery. 4. An inquiry into the state of the ancient measures. 5. *De Valentinianorum heresi conjectura*. 6. Several sermons; and other works.

HOOPING-COUGH. See (the Index subjoined to) MEDICINE.

HOOPOE. See UPUPA.

HOORNBECK (John), professor of divinity in the universities of Leyden and Utrecht, was born at Haerlem in 1617. He understood the Latin, Hebrew, Chaldaic, Syriac, Rabbinical, Dutch, German, English, French, and Italian languages; and published many works, among which are, 1. A refutation of Socinianism, in 3 vols 4to. 2. A treatise for the conviction of the Jews. 3. Of the conversion of the Heathens. 4. Theological institutions, &c. which are written in Latin. Mr Bayle represents him as a complete model of a good pastor and divinity professor.

HOP, in botany. See HUMULUS.

HOPS were first brought into England from the Netherlands in the year 1524. They are first mentioned in the English statute-book in the year 1552, viz. in the 5 and 6 of Edw. VI. cap. 5. And by an act of parliament of the first year of king James I. anno 1603, cap. 18. it appears, that hops were then produced in abundance in England.

The hop being a plant of great importance in the article of brewing, we shall consider what relates to the culture and management of it, under the following heads:

Of Soil. As for the choice of their hop-grounds, they esteem the richest and strongest grounds the most proper; and if it be rocky within two or three feet of the surface the hops will prosper well; but they will by no means thrive on a stiff clay or spongy wet land.

The Kentish planters account new land best for hops; they plant their hop-gardens with apple-trees at a large distance, and with cherry-trees between; and when the land hath done its best for hops, which they reckon it will in about 10 years, the trees may begin to bear. The cherry-trees last about 30 years, and by that time the apple-trees are large, they cut down the cherry-trees.

The Essex planters account a moory land the most proper for hops.

As to the situation of a hop-ground, one that inclines to the south or west is the most eligible; but if it be exposed to the northeast or southwest winds, there should be a shelter of some trees at a distance, because the northeast winds are apt to nip the tender shoots in the spring; and the southwest winds frequently break and blow down the poles at the latter end of the summer, and very much endanger the hops.

In the winter-time provide your foil and manure for the hop-ground against the following spring.

If the dung be rotten, mix it with two or three parts of common earth, and let it incorporate together till

Hooping,

Hops.

Hops.

you have occasion to make use of it in making your hop hills; but if it be new dung, then let it be mixed as before till the spring in the next year, for new dung is very injurious to hops.

Dung of all sorts was formerly more commonly made use of than it is now, especially when rotted and turned to mould, and they who have no other manure must use it; which if they do, cows or hogs-dung, or human ordure mixed with mud, may be a proper compost, because hops delight most in a manure that is cool and moist.

Planting. Hops require to be planted in a situation so open, as that the air may freely pass round and between them, to dry up and dissipate the moisture, whereby they will not be so subject to fire-blasts, which often destroy the middles of large plantations, while the outsidings remain unhurt.

As for the preparation of the ground for planting, it should, in the preceding winter, be plowed and harrowed even; and then lay upon it in heaps a good quantity of fresh rich earth, or well-rotted dung and earth mixed together, sufficient to put half a bushel in every hole to plant the hops in, unless the natural ground be very fresh and good.

The hills where the hops are to be planted should be eight or nine feet asunder, that the air may freely pass between them; for in close plantations, they are very subject to what the hop-planters call the *fire-blast*.

If the ground is intended to be ploughed with horses between the hills, it will be best to plant them in squares chequerwise; but if the ground is so small that it be may done with the breast-plough or spade, the holes should be ranged in a quincunx form. Which way soever you make use of, a stake should be stuck down at all the places where the hills are to be made.

Persons ought to be very curious in the choice of the plants as to the kind of hop; for if the hop-garden be planted with a mixture of several sorts of hops that ripen at several times, it will cause a great deal of trouble, and be a great detriment to the owner.

The two best sorts are the white and the grey bind; the latter is a large square hop, more hardy, and is the more plentiful bearer, and ripens later than the former.

There is also another sort of the white bind, which ripens a week or ten days before the common; but this is tenderer, and a less plentiful bearer; but it has this advantage, that it comes first to market.

But if three grounds, or three distant parts of one ground, be planted with these three sorts, there will be this conveniency, that they may be picked successively as they become ripe. The sets should be five or six inches long, with three or more joints or buds on them.

If there be a sort of hop you value, and would increase plants and sets from, the superfluous binds may be laid down when the hops are tied, cutting off the tops, and burying them in the hill; or when the hops are dressed, all the cuttings may be saved; for almost every part will grow, and become a good set the next spring.

As to the seasons of planting hops, the Kentish planters best approve the months of October and March, both which sometimes succeed very well; but the sets are not to be had in October, unless from

VOL. VIII. Part II.

some ground that is to be destroyed; and likewise there is some danger that the sets may be rotted, if the winter prove very wet; therefore the most usual time of procuring them is in March, when the hops are cut and dressed.

As to the manner of planting the sets, there should be five good sets planted in every hill, one in the middle, and the rest round about sloping, the tops meeting at the centre; they must stand even with the surface of the ground; let them be pressed close with the hand, and covered with fine earth, and a stick should be placed on each side the hill to secure it.

The ground being thus planted, all that is to be done more during that summer, is to keep the hills clear from weeds, and to dig up the ground about the month of May, and to raise a small hill round about the plants. In June you must twist the young bind or branches together into a bunch or knot; for if they are tied up to small poles the first year, in order to have a few hops from them, it will not countervail the weakening of the plants.

A mixture of compost or dung being prepared for your hop ground, the best time for laying it on, if the weather prove dry, is about Michaelmas, that the wheels of the dung cart may not injure the hops, nor furrow the ground: if this be not done then, you must be obliged to wait till the frost has hardened the ground, so as to bear the dung cart; and this is also the time to carry on your new poles, to recruit those that are decayed, and to be cast out every year.

If you have good store of dung, the best way will be to spread it in the alleys all over the ground, and to dig it in the winter following. The quantity they will require will be 40 loads to an acre, reckoning about 30 bushels to the load.

If you have not dung enough to cover all the ground in one year, you may lay it on one part one year, and on the rest in another, or a third; for there is no occasion to dung the ground after this manner oftener than once in three years.

Those who have but a small quantity of dung, usually content themselves with laying on about twenty loads upon an acre every year; this they lay only on the hills, either about November, or in the spring; which last some account the best time, when the hops are dressed, to cover them after they are cut; but if it be done at this time, the compost or dung ought to be very well rotted and fine.

Dressing. As to the dressing of the hops, when the hop-ground is dug in January or February, the earth about the hills, and very near them, ought to be taken away with a spade, that you may come the more conveniently at the stock to cut it.

About the end of February, if the hops were planted the spring before, or if the ground be weak, they ought to be dressed in dry weather; but else, if the ground be strong and in perfection, the middle of March will be a good time; and the latter end of March, if it be apt to produce over-rank binds, or the beginning of April may be soon enough.

Then having with an iron picker cleared away all the earth out of the hills, so as to clear the stock to the principal roots, with a sharp knife you must cut off all the shoots which grew up with the binds the last year; and also all the young suckers, that none be left to run

4 M

in

Hops.

Hops. in the alley, and weaken the hill. It will be proper to cut one part of the stock lower than the other, and also to cut that part low that was left highest the preceding year. By pursuing this method you may expect to have stronger buds, and also keep the hill in good order.

In dressing those hops that have been planted the year before, you ought to cut off both the dead tops and the young suckers which have sprung up from the sets, and also to cover the stocks with fine earth a finger's length in thickness.

The poling. About the middle of April the hops are to be poled, when the shoots begin to sprout up; the poles must be set to the hills deep into the ground, with a square iron picker or crow, that they may the better endure the winds; three poles are sufficient for one hill. These should be placed as near the hill as may be, with their bending tops turned outwards from the hill, to prevent the binds from entangling; and a space between two poles ought to be left open to the south to admit the sun-beams.

The poles ought to be in length 16 or 20 feet, more or less according as the ground is in strength; and great care must be taken not to overpole a young or weak ground, for that will draw the stock too much, and weaken it. If a ground be overpoled, you are not to expect a good crop from it; for the branches which bear the hops will grow very little till the binds have over-reached the poles, which they cannot do when the poles are too long. Two small poles are sufficient for a ground that is young.

If you wait till the sprouts or young binds are grown to the length of a foot, you will be able to make a better judgment where to place the largest poles; but if you stay till they are so long as to fall into the alleys, it will be injurious to them, because they will entangle one with another, and will not clasp about the pole readily.

Maple or aspen poles are accounted the best for hops, on which they are thought to prosper best, because of their warmth; or else, because the climbing of the hop is promoted by means of the roughness of the bark. But for durability, aspen or willow poles are preferable; but chestnut poles are the most durable of all.

If after the hops are grown up you find any of them have been under-poled, taller poles may be placed near those that are too short to receive the binds from them.

The tying. As to the tying of hops, the buds that do not clasp of themselves to the nearest pole when they are grown to three or four feet high, must be guided to it by the hand, turning them to the sun, whose course they will always follow. They must be bound with withered rushes, but not so close as to hinder them from climbing up the pole.

This you must continue to do till all the poles are furnished with binds, of which two or three are enough for a pole; and all the sprouts and binds that you have no occasion for, are to be plucked up; but if the ground be young, then none of these useless binds should be plucked up, but should be wrapt up together in the middle of the hill.

When the binds are grown beyond the reach of your hands, if they forsake the poles, you should make use of a stand-ladder in tying them up.

Towards the latter end of May, when you have made an end of tying them, the ground must have the summer dressing: this is done by casting up with the spade some fine earth into every hill; and a month after this is done, you must hoe the alleys with a Dutch hoe, and make the hills up to a convenient bigness.

Gathering. About the middle of July hops begin to blow, and will be ready to gather about Bartholomew Tide. A judgment may be made of their ripeness by their strong scent, their hardness, and the brownish colour of their seed.

When by these tokens they appear to be ripe, they must be picked with all the expedition possible; for if at this time a storm of wind should come, it would do them great damage by breaking the branches, and bruising and discolouring the hops; and it is very well known that hops, being picked green and bright, will sell for a third part more than those which are discoloured and brown.

The most convenient way of picking them is into a long square frame of wood, called a *bin*, with a cloth hanging on tenter-hooks within it, to receive the hops as they are picked.

The frame is composed of four pieces of wood joined together, supported by four legs, with a prop at each end to bear up another long piece of wood, placed at a convenient height over the middle of the bin; this serves to lay the poles upon which are to be picked.

This bin is commonly eight feet long, and three feet broad; two poles may be laid on it at a time, and six or eight persons may work at it, three or four on each side.

It will be best to begin to pick the hops on the east or north side of your ground, if you can do it conveniently; this will prevent the south west wind from breaking into the garden.

Having made choice of a plot of the ground containing 11 hills square, place the bin upon the hill which is in the centre, having five hills on each side; and when these hills are picked, remove the bin into another piece of ground of the same extent, and so proceed till the whole hop-ground is finished.

When the poles are drawn up to be picked, you must take great care not to cut the binds too near the hills, especially when the hops are green, because will make the sap to flow excessively.

The hops must be picked very clean, *i. e.* free from leaves and stalks; and, as there shall be occasion, two or three times in a day the bin must be emptied into a hop-bag made of coarse linen cloth, and carried immediately to the oast or kiln in order to be dried; for if they should be long in the bin or bag, they will be apt to heat and be discoloured.

If the weather be hot, there should no more poles be drawn than can be picked in an hour, and they should be gathered in fair weather, if it can be, and when the hops are dry; this will save some expence in firing, and preserve their colour better when they are dried.

The crop of hops being thus bestowed, you are to take care of the poles against another year, which are best to be laid up in a shed, having first stripped off the haulm from them; but if you have not that convenience,

Hops.

ency, set up three poles in the form of a triangle, or six poles (as you please) wide at bottom; and having set them into the ground, with an iron picker, and bound them together at the top, set the rest of your poles about them; and being thus disposed, none but those on the outside will be subject to the injuries of the weather, for all the inner poles will be kept dry, unless at the top; whereas, if they were on the ground, they would receive more damage in a fortnight than by their standing all the rest of the year.

Drying. The best method of drying hops is with charcoal on an oast or kiln, covered with hair-cloth, of the same form and fashion that is used for drying malt. There is no need to give any particular directions for making these, since every carpenter or bricklayer in those countries where hops grow, or malt is made, knows how to build them.

The kiln ought to be square, and may be of 10, 12, 14, or 16 feet over at the top, where the hops are laid, as your plantation requires, and your room will allow. There ought to be a due proportion between the height and breadth of the kiln and the beguels of the steddle where the fire is kept, viz. if the kiln be 12 feet square on the top, it ought to be nine feet high from the fire, and the steddle ought to be six feet and a half square, and so proportionable in other dimensions.

The hops must be spread even upon the oast a foot thick or more, if the depth of the curb will allow it; but care is to be taken not to overload the oast if the hops be green or wet.

The oast ought to be first warmed with a fire before the hops are laid on, and then an even steady fire must be kept under them; it must not be too fierce at first, lest it scorch the hops, nor must it be suffered to sink or slacken, but rather be increased till the hops be nearly dried, lest the moisture or sweat which the fire has raised fall back or discolour them. When they have lain about nine hours they must be turned, and in two or three hours more they may be taken off the oast. It may be known when they are well dried by the brittleness of the stalks and the easy falling off of the hop leaves.

It is found by experience that the turning of hops, though it be after the most easy and best manner, is not only an injury or waste to the hops, but also an expence of fuel and time, because they require as much fuel and as long a time to dry a small quantity, by turning them, as a large one. Now this may be prevented by having a cover (to be let down and raised at pleasure) to the upper bed whereon the hops lie. This cover may also be tinned, by nailing single tin plates over the face of it; so that when the hops begin to dry, and are ready to burn, i. e. when the greatest part of their moisture is evaporated, then the cover may be let down within a foot or less of the hops (like a reverberatory), which will reflect the heat upon them, so that the top will soon be as dry as the lowermost, and every hop be equally dried.

Bagging. As soon as the hops are taken off the kiln, lay them in a room for three weeks or a month to cool, give, and toughen; for if they are bagged immediately they will powder, but if they lie a while (and the longer they lie the better, provided they be covered close with blankets to secure them from the

air) they may be bagged with more safety, as not being liable to be broken to powder in treading; and this will make them bear treading the better, and the harder they are trodden the better they will keep.

The common method of bagging is as follows: they have a hole made in an upper floor, either round or square, large enough to receive a hop-bag, which consists of four ells and a half of ell-wide cloth, and also contains ordinarily two hundred and a half of hops; they tie a handful of hops in each lower corner of the bag to serve as handles to it; and they fasten the mouth of the bag, so placed that the hoop may rest upon the edges of the hole.

Then he that is to tread the hops down into the bag, treads the hops on every side, another person continually putting them in as he treads them till the bag is full; which being well filled and trodden, they unrip the fastening of the bag to the hoops, and let it down, and close up the mouth of the bag, tying up a handful of hops in each corner of the mouth, as was done in the lower part.

Hops being thus packed, if they have been well dried, and laid up in a dry place, will keep good several years; but care must be taken that they be neither destroyed nor spoiled by the mice making their nests in them.

Produce. The charge of an acre of hop-ground in most parts of England where hops are cultivated, is computed thus: three pounds for the husbandry, four pounds for the wear of the poles, five pounds for picking and drying, one pound ten shillings for dung, one pound for rent, though in some places they pay four or five pounds an acre yearly for the rent of the land, and ten shillings for tythe; in all L. 15 a year. The hop-planters in England reckon that they have but a moderate return, when the produce of an acre of hops does not sell for more than L. 30. They frequently have fifty, sixty, eighty, or a hundred pounds; and in a time of general scarcity considerably more: so that, upon the whole, if the total charge of an acre of hops is computed at fifteen pounds a year, and its average produce at thirty pounds, the clear profit from an acre will be fifteen pounds a year. But the plantation of hops has lately so much increased, and the average produce so much exceeded the consumption, that hops have been with many planters rather a losing than a very profitable article.

Uses. In the spring-time, while the bud is yet tender, the tops of the plant being cut off, and boiled, are ate like asparagus, and found very wholesome, and effectual to loosen the body; the heads and tendrils are good to purify the blood in the scurvy, and most cutaneous diseases; decoctions of the flowers, and syrups thereof, are of use against pestilential fevers; juleps and apozems are also prepared with hops for hypochondriacal and hysterical affections, and to promote the menses.

A pillow stuffed with hops and laid under the head, is said to procure sleep in fevers attended with a delirium. But the principal use of hops is in the brewery for the preservation of malt liquors; which by the superaddition of this balsamic, aperient, and diuretic bitter, become less viscid, less apt to turn sour, more detergent, more disposed to pass off by urine, and in general more salubrious. They are said to contain an

Hops.

Hops,
Hope.

agreeable odoriferous principle, which promotes the vinous fermentation. When slightly boiled or infused in warm water, they increase its spirituousity.

Laws relating to Hops. By 9 Anne, cap. 121. an additional duty of 3d a pound is laid on all hops imported, over and above all other duties; and hops landed before entry and payment of duty, or without warrant for landing, shall be forfeited and burnt; the ship also shall be forfeited, and the person concerned in importing or landing shall forfeit 5 l. a hundred weight. 7 Geo. II. cap. 19. By 9 Anne, cap. 12. there shall be paid a duty of 1d. for every pound of hops grown in Great Britain, and made fit for use, within six months after they are cured and bagged; and hop-grounds are required to be entered on pain of 40s. an acre. Places of curing and keeping are also to be entered, on pain of 50l. which may be visited by an officer at any time without obstruction, under the penalty of 20l. All hops shall, within six weeks after gathering, be brought to such places to be cured and bagged, on pain of 5s. a pound. The re-bagging of foreign hops in British bagging for sale or exportation, incurs a forfeiture of 10l. a hundred weight; and defrauding the king of his duty by using twice or oftener the same bag, with the officer's mark upon it, is liable to a penalty of 40l. The removal of hops before they have been bagged and weighed, incurs a penalty of 50l. Concealment of hops subjects to the forfeiture of 20l. and the concealed hops; and any person who shall privately convey away any hops, with intent to defraud the king and owner, shall forfeit 5s. a pound. And the duties are required to be paid within six months after curing, bagging, and weighing, on pain of double duty, two-thirds to the king, and one-third to the informer. No common brewer, &c. shall use any bitter ingredient instead of hops, on pain of 20l. Hops which have paid the duty may be exported to Ireland; but by 6 Geo. II. cap. 11. there shall be no drawback; and by 7 Geo. II. cap. 19. no foreign hops shall be landed in Ireland. Notice of bagging and weighing shall be sent in writing to the officer, on pain of 50l. 6 Geo. cap. 21. And by 14 Geo. III. cap. 68. the officer shall, on pain of 5l. weigh the bags or pockets, and mark on them the true weight or tare, the planter's name, and place of abode, and the date of the year in which such hops were grown; and the altering or forging, or obliterating such mark, incurs a forfeiture of 10l.—The owners of hops shall keep at their oasts, &c. just weights and scales, and permit the officer to use them on pain of 20l. 6 Geo. cap. 21. And by 10 Geo. III. cap. 44. a penalty of 100l. is inflicted for false scales and weights. The owners are allowed to use casks instead of bags, under the same regulations. 6 Geo. cap. 21. If any person shall mix with hops any drug to alter the colour or scent, he shall forfeit 5l. a hundred weight. If any person shall unlawfully and maliciously cut hop binds growing on poles in any plantation, he shall be guilty of felony without benefit of clergy. 6 Geo. II. cap. 37. By a late act, five *per cent.* is added to the duties on hops.

HOPE (Dr John), professor of botany in the university of Edinburgh, was born at Edinburgh on the 10th of May 1725. He was the son of Mr Robert Hope a respectable surgeon, whose father, Lord Rankeilar, made a distinguished figure as one of the sena-

tors of the college of justice in the kingdom of Scotland. By his mother he was descended from the ancient family of Glas of Sauchie in Stirlingshire. After finishing the usual course of school education, he entered to the university of Edinburgh; and having, as it were, an hereditary predilection for the healing art, his attention was soon particularly directed to that branch of science. Having finished his academical education at Edinburgh, he visited other medical schools; and upon his return to his native country, he obtained the degree of Doctor of Medicine from the university of Glasgow in the beginning of the year 1750. A few months after that, he was admitted a member of the royal college of physicians in Edinburgh, and entered upon the practice of medicine in this city. After he had continued about ten years in practice, discharging the duties of his profession with a degree of judgment, attention, and humanity, which did him great honour; by the death of Dr Alston the botanical chair in the university became vacant; when Dr Hope, by a commission from his sovereign, dated the 13th of April 1761, was appointed king's botanist for Scotland and superintendant of the royal garden at Edinburgh. A few weeks after this he was elected by the town-council of Edinburgh as the successor of Dr Alston in the professorships both of botany and materia medica; and thus he became one of the members of the faculty of medicine in the university. After he had continued for about six years to give regular courses of lectures on these subjects, with no less credit to himself than benefit to his hearers, teaching the one branch during the summer, and the other during the winter months, he found that his health was considerably impaired; which induced him to form the resolution of resigning the materia medica, and of afterwards solely confining his labours as a teacher to his favourite science of botany. This resolution he carried into effect in the year 1768; and by a new commission from his majesty, dated the 8th of May, he was nominated regius professor of medicine and botany in the university, and had the offices of king's botanist and superintendant of the royal garden conferred upon him for life, which till that time had been always granted during pleasure only.

Dr Hope's predecessor, although a learned and worthy man, could never obtain sufficient public funds for the establishment of a proper botanical garden at Edinburgh; and from the situation as well as the extent of the garden at that time, joined to the smallness of its conservatories for plants, it could boast of no riches in the way of exotics. The only field for improvement, therefore, to the botanical student, was the environs of Edinburgh, to which it must indeed be allowed that nature has been uncommonly liberal, in affording a very great variety of indigenous vegetables. In this situation, the establishment of a new garden naturally suggested itself as a grand and important object; and it was accomplished by the zeal and industry of Dr Hope, aided by the munificence of his present majesty. The first assistance given to the undertaking was under the administration of Lord Bute; and afterwards, under that of the duke of Portland, a permanent fund for the support of the botanical garden at this place was established, which may render it not inferior to any in Europe. Dr Hope's unwearied ex-

Hope.

Hope.

ertions in procuring for the garden the vegetable productions of every climate, could not be exceeded. His endeavours were constantly directed in adding not to the show, but to the riches of the garden; and they were employed with such success, that in a very short time the intelligent botanist might gratify his curiosity, in contemplating the rarest plants of every country which has yet been explored. Nor were his industrious exertions more assiduously bestowed in forming and enriching the garden, than in cherishing and promoting a zeal for botanical studies. From but a very small number of lectures, which were all that his predecessor ever gave, he gradually prolonged the course till it became as complete as any one delivered at this place; and during all this extended course, he taught in such a manner, as clearly demonstrated a degree of ardour and enthusiasm in himself, which could hardly fail to inspire similar emotions in others. But even such precept, and such example, were not the only means he employed for directing the attention of the industrious, ingenious, and laudably ambitious student, to this branch of science. By bestowing, entirely at his own expence, an annual gold medal, as a testimony of superior merit, he gave a spur to exertion, from which the toils of study were alleviated by the love of fame, and the labours of industry converted into the pleasures of emulation.

Dr Hope married the daughter of Dr Stevenson an eminent physician in Edinburgh; by whom he had four sons and one daughter. He died in November 1786. He was a member not only of the Royal Society of London, but also of several foreign societies; and at the time of his death he held the distinguished office of president of the royal college of physicians. Dr Hope, with whom it was a principal object to make botany subservient to the arts more immediately useful to life, and particularly to medicine, was one of the first who, in conjunction with the late Sir Alexander Dick, turned his attention to the practical cultivation of rhubarb in Britain; and he demonstrated the facility with which it might be multiplied. He lived to see it cultivated in such abundance, that the British market was no longer under any necessity of depending upon foreign climates for this valuable and once expensive medicine; also he has shown, that the *asafetida* plant, by proper attention, not only bears the vicissitudes of our climate, but grows in such a vigorous and healthful state as to be fully impregnated with its active gum. There is therefore reason to hope, that by the exertions of future industry, the shop of the apothecary may be supplied with this article also from his own garden. Besides being the author of some papers in the Philosophical Transactions, particularly two respecting the useful plants just mentioned, Dr Hope had in contemplation a more extensive botanical work, on which he had bestowed much study and reflection. It was his wish to increase those advantages which result from the very ingenious and useful artificial arrangement of Linnæus, by conjoining it with a system of vegetables distributed according to their great natural orders. For this purpose, no inconsiderable part of that time which he could spare from other unavoidable engagements was employed in attempts to improve and perfect natural method in the arrangement of vegetables. In this work he had made very

considerable progress; and it must be the subject of sincere regret to every lover of botany, if from the event of his death the public shall be for ever deprived of those fruits of his labours.

HOPE, in ethics, is the desire of some good, attended with a belief of the possibility, at least, of obtaining it, and enlivened with joy, greater or less, according to the greater or less probability of our possessing the object of our hope. Alexander, preparing for his Asian expedition, distributed his hereditary dominions among his friends; allotting to some villages, to others boroughs, to others cities; and being asked what he had reserved for himself, replied, Hope.

Good-Hope. See *Good-Hope*.

HOPEA, in botany: A genus of the polyandria order, belonging to the polydelphia class of plants. The calyx is quinquefid, superior; the corolla pentapetalous; the stamina are many and coalited into five pencils; there is one style; the fruit is a plum with a trilocular kernel. There is only one species, the *tinctora*, a native of Carolina.

HOPKINS (Ezekiel), bishop of Derry in Ireland, was the son of an obscure clergyman in Devonshire; and was for some time a chorister of Magdalen college, Oxford, and usher of the adjoining school. He was afterwards a Presbyterian minister, and was extolled as an excellent preacher. John, lord Roberts, happening to hear him preach, was so pleased with his person, his discourse, and his manner, that he retained him as his chaplain when he was sent in quality of lord lieutenant into Ireland, and preferred him to the deanery of Raphoe; and on his being recalled, so strongly recommended him to his successor, that he was soon preferred to the bishopric at Raphoe, whence he was translated to Derry. During the war under the earl of Tyrconnel at the revolution, he withdrew into England; and was chosen minister of St Mary, Aldermanbury, in London, where he died in 1690. His sermons, his exposition of the ten commandments, and that of the Lord's prayer, are much esteemed. His works were printed together in 1710, folio. He was the father of Mr Charles Hopkins, several of whose poetical pieces are in Dryden's Miscellanies.

HOPLITES, HOPLITÆ (formed of *οπλον* armour), in antiquity, were such of the candidates at the Olympic and other sacred games as ran races in armour.

One of the finest pieces of the famous Parrhasius was a painting which represented two hoplites; the one running, and seeming to sweat large drops; the other laying his arms down, as quite spent and out of breath.

HOPLITODROMOS (formed of *οπλον* armour, and *δρομα* I run), in the ancient gymnastic sports, a term applied to such persons as went through those toilsome and robust exercises in complete armour; by which the exercise became much more violent, and the wearing of armour in the time of battle much more easy.

HOPLOMACHI, *οπλομαχοι* (composed of *οπλον* armour, and *μαχομαι* I fight), in antiquity, were a species of gladiators who fought in armour; either completely armed from head to foot, or only with a cask and cuirass.

HOPPER, a vessel wherein seed-corn is carried at the time of sowing.

Hope
||
Hopper.

The

Hor
||
Horatius.

The word is also used for that wooden trough in a mill, into which the corn is put to be ground.

HOR, a mountain, or mountainous tract of Arabia Petræa, situated in that circuit which the Israelites took to the south and south-east of Edom in their way to the borders of Moab: on this mountain Aaron died. The inhabitants were called *Horites*. This tract was also called *Seir*, either from a native Horite, or from Esau, by way of anticipation from his hairy habit of body; whose posterity drove out the Horites.

HORÆ. See HOURS.

HORÆA, in antiquity, solemn sacrifices, consisting of fruits, &c. offered in spring, summer, autumn, and winter; that heaven might grant mild and temperate weather. These, according to Meursius, were offered to the goddesses called *Ἵρας*, i. e. *Hours*, who were three in number, attended upon the Sun, presided over the four seasons of the year, and had divine worship paid them at Athens.

HORAPOLLO, or HORUS APOLLO, a grammarian of Panopolis in Egypt, according to Suidas, who first taught at Alexandria, and then at Constantinople under the reign of Theodosius. There are extant under his name, two books on the hieroglyphics of the Egyptians; which Aldus first published in Greek in 1505, in folio; and they have often been published since, with a Latin version and notes. It is not certain, however, that the grammarian of Alexandria was the author of these books; they being rather thought to belong to another Horapollon of more ancient date: on which head, see *Fabricius's Bibliotheca Græca*.

HORATII, three Roman brothers, who, under the reign of Tullus Hostilius, fought against the three Curiatii, who belonged to the Albanian army. Two of the Horatii were first killed; but the third, by his address, successively slew the three Curiatii, and by this victory rendered the city of Alba subject to the Romans. See ROME.

HORATIUS, surnamed *Cocles* from his losing an eye in combat, was nephew to the consul Horatius Pulvillus, and descended from one of the three brothers who fought against the Curiatii. Porfenna, laying siege to Rome, drove the Romans from Janiculum; and pursued them to the wooden bridge over the Tiber, which joined the city to Janiculum. Largius, Herminius, and Horatius Cocles, sustained the shock of the enemy on the bridge, and prevented their entering the city with the Romans; but Largius and Herminius having passed the bridge, Horatius Cocles was left alone, and repulsed the enemy till the bridge was broken under him: he then threw himself armed into the Tyber, swam across the river, and entered Rome in triumph.

HORATIUS (Quintus Flaccus), the most excellent of the Latin poets of the lyric and satirical kind, and the most judicious critic in the reign of Augustus, was the grandson of a freedman, and was born at Venusium 64 B. C. He had the best masters in Rome, after which he completed his education at Athens. Having taken up arms, he embraced the party of Brutus and Cassius, but left his shield at the battle of Philippi. Some time after, he gave himself up entirely to the study of polite literature and poetry. His ta-

lents soon made him known to Augustus and Mecænas, who had a particular esteem for him, and loaded him with favours. Horace also contracted a strict friendship with Agrippa, Pollio, Virgil, and all the other great men of his time. He lived without ambition, and led a tranquil and agreeable life with his friends; but was subject to a defluxion in his eyes. He died at the age of 57. There are still extant his Odes, Epistles, Satires, and Art of Poetry; of which there have been a great number of editions. The best are those of the Louvre, in 1642, folio; of Paris, 1691, quarto; of Cambridge, 1699; and that with Bentley's emendations, printed at Cambridge in 1711.

HORD, in geography, is used for a company of wandering people, which have no settled habitation, but stroll about, dwelling in waggons or under tents, to be ready to shift as soon as the herbage, fruit, and the present province, is eaten bare: such are several tribes of the Tartars, particularly those who inhabit beyond the Wolga, in the kingdom of Astracan and Bulgaria.

A hord consists of 50 or 60 tents, ranged in a circle, and leaving an open place in the middle. The inhabitants in each hord usually form a military company or troop, the eldest whereof is commonly the captain, and depends on the general or prince of the whole nation.

HORDEUM, BARLEY, in botany: A genus of the digynia order, belonging to the triandria class of plants; and in the natural method ranking under the 4th order, *Gramina*. The calyx is lateral, bivalved, unisporous, and triple. The involucre consists of six leaves, and contains three flowers. There are eight species; only one of which, viz. the murinum, or wall-barley-grass, is a native of Britain. The native place of the vulgare, or common barley cultivated in our fields, is not known. For the culture, &c. of common barley, see AGRICULTURE, n° 139—146.

HORDICALIA, or HORDICIDIA, in antiquity, a religious feast held among the Romans, wherein they sacrificed cattle big with young. This feast fell on April 15. on which day they sacrificed 30 cows with calf to the goddess Tellus or the Earth; part of them were sacrificed in the temple of Jupiter. The calves taken out of their bellies were burnt to ashes at first by the pontifices, afterwards by the eldest of the vestal virgins.

HOREB, or OREB, a mountain of Arabia Petræa, contiguous to and on the south side of mount Sinai; the scene of many miraculous appearances.

HORESTI (Tacitus), a people of Britain, beyond Solway Frith. Now *Eskdale* (Camden).

HORITES, an ancient people, who at the beginning dwelt in the mountains of Seir beyond Jordan (Gen. xiv. 6.) They had princes, and were powerful, even before Esau made a conquest of their country, (*id.* xxxvi. 20—30.) The Horites, the descendants of Seir, and the Edomites, seem afterwards to have been confounded, and to have composed but one people (Deut. ii. 2. xxxiii. 2. and Judg. v. 4.) They dwelt in Arabia Petræa, and Arabia Deserta, to the south-east of the promised land. We find the Hebrew word *חורים* *Chorim*, which in the book of Genesis is translated *Horites*, to be used in an appellative sense in several other passages of scripture, and to signify nobles,

Hord
||
Horites.

Horehound bles, or great and powerful men (1 Kings xxi. 8, 11. and Neh. ii. 16. iv. 14. v. 7. vi. 17. vii. 5. xii. 17. Eccl. x. 17. Isa. xxxiv. 12. Jer. xxvii. 20. xxxix. 6.); and it is very probable that the Greeks derived from hence their *heroes* in like manner as they derived *Anax* "a king," from the sons of Anak, the famous giant in Palestine.

HOREHOUND, *BALLOTA*, or *Stachys*, in botany. See *MARRUBIUM*.

HORIZON, or *HORISON*, in geography and astronomy, a great circle of the sphere, dividing the world into two parts or hemispheres; the one upper and visible, the other lower and hid. The word is pure Greek, *οριζων*, which literally signifies "bounding or terminating the sight;" being formed of *οριζω*, *termino*, *definio*, "I bound, I limit;" whence it is also called *finitor*, "finisher." See *ASTRONOMY* and *GEOGRAPHY*.

The horizon is either *rational* or *sensible*.

Rational, *true*, or *astronomical HORIZON*, which is also called simply and absolutely *the horizon*, is a great circle, whose plane passes through the centre of the earth, and whose poles are the zenith and nadir. It divides the sphere into two equal parts or hemispheres.

Sensible, *visible*, or *apparent HORIZON*, is a lesser circle of the sphere, which divides the visible part of the sphere from the invisible. Its poles, too, are the zenith and nadir: and consequently the *sensible horizon* is parallel to the *rational*; and it is cut at right angles, and into two equal parts, by the verticals.---The *sensible horizon* is divided into *eastern* and *western*. The *eastern* or *ortive horizon*, is that part of the horizon wherein the heavenly bodies rise. The *western* or *occidental horizon*, is that wherein the stars set. The altitude or elevation of any point of the sphere, is an arch of a vertical circle intercepted between it and the sensible horizon.

By *sensible horizon* is also frequently meant a circle; which determines the segment of the surface of the earth, over which the eye can reach; called also the *physical horizon*. In this sense we say, a spacious *horizon*, a narrow scanty *horizon*.

HORIZONTAL, something that relates to the horizon, is taken in the horizon, or on a level with the horizon.---We say, a *horizontal plane*, *horizontal line*, &c.

HORIZONTAL Dial, is that drawn on a parallel to the horizon: having its gnomon, or style, elevated according to the altitude of the pole of the place it is designed for. Horizontal dials are, of all others, the most simple and easy. The manner of describing them, see under the article *DIAL*.

HORIZONTAL Line, in perspective, is a right line drawn through the principal point, parallel to the horizon: or, it is the intersection of the horizontal and perspective planes. See *PERSPECTIVE*.

HORIZONTAL Plane, is that which is parallel to the horizon of the place, or nothing inclined thereto.

The business of levelling is to find whether two points be in the horizontal plane; or how much the deviation is. See *LEVELLING*.

HORIZONTAL Plane, in perspective, is a plane parallel to the horizon, passing through the eye, and cutting the perspective plane at right angles.

HORIZONTAL Projection. See *GEOGRAPHY*, n^o 66, 69. **HORIZONTAL Range**, or *Level Range*, of a piece of ordnance, is the line it describes, when directed parallel to the horizon or horizontal line. See *GUNNERY*, *passim*.

HORIZONTAL Moon. See *ASTRONOMY*, n^o 374.

HORIZONTAL Speculum. See *SPECULUM*.

HORMINUM, *CLARY*, in botany: A genus of the gymnospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 4th order, *Verticillate*. The calyx is campanulated, with four segments nearly equal, the fourth larger, and emarginated; the upper lip of the corolla concave. There are several species; the most remarkable of which is the verbenaceum, or common wild clary. It grows naturally on sandy and gravelly ground in many parts of Britain. It has sometimes been called *oculus Christi*, from the supposed virtues of its seeds in clearing the sight, which it does by its viscous covering; for when any thing happens to fall into the eye, if one of the seeds is put in at one corner, and the eyelid kept close over it, moving the seed gently along the eye, whatever happens to be there will stick to it, and so be brought out. The virtues of this are supposed to be the same as those of the garden clary, but not quite so powerful.

HORN, in physiology, a hard substance growing on the heads of divers animals, particularly the cloven-footed quadrupeds; and serving them both as weapons of offence and defence.

The horn of animals is of the same nature as their gelatinous matter; and is only that matter charged with a less quantity of water, and a larger quantity of earth, and sufficiently condensed to have a firm and solid consistence. By digesting horn with water in Papin's digester, it may be entirely converted into jelly.

Horn is a perfectly animalised matter, and furnishes in distillation the same principles as all animal matters; that is, at first a pure phlegm, with a degree of heat not exceeding that of boiling water; then a volatile alkaline spirit, which becomes more and more penetrating and strong; a fetid, light, and thin oil; a concrete volatile salt, which forms ramifications upon the sides of the receiver; much air; fetid oil, which becomes more and more black and thick; and lastly, it leaves in the retort a considerable quantity of almost incombustible coal, from which, after its incineration, scarcely any fixed alkali can be obtained.

Animal oil, and particularly that which is drawn first in the distillation of horn, is susceptible of acquiring great thinness and volatility by repeated distillations, and is then called the *oil of dippel*.

The horns of stags, and of other animals of that kind, are the most proper to furnish the animal oil to be rectified in the manner of dippel; because they yield the largest quantity. These horns also differ from the horns of other animals in this, that they contain a larger quantity of the same kind of earth which is in bones; hence they seem to possess an intermediate nature betwixt horns and bones.

Hart's HORN. See *HART'S HORN*.

HORNS make a considerable article in the arts and manufactures. Bullocks horns, softened by the fire, serve to make lanthorns, combs, knives, ink horns, tobacco boxes, &c.

Horn.

Dyeing of Horn—Black is performed by steeping brags in aqua-fortis till it be returned green: with this the horn is to be washed once or twice, and then put into a warmed decoction of logwood and water. Green is begun by boiling it, &c. in alum-water; then with verdigrise, ammoniac, and white-wine vinegar; keeping it hot therein till sufficiently green. Red is begun by boiling it in alum-water, and finished by decoction in a liquor compounded of quick-lime steeped in rain water, strained, and to every pint an ounce of Brazil-wood added. In this decoction the bone, &c. is to be boiled till sufficiently red.

Dr Lewis informs us that horns receive a deep black stain from solution of silver. It ought to be diluted to such a degree as not sensibly to corrode the subject; and applied two or three times, if necessary, at considerable intervals, the matter being exposed as much as possible to the sun, to hasten the appearance and deepening of the colour.

Dyeing or staining Horn to imitate Tortoise-shell.—The horn to be dyed must be first pressed into proper plates, scales, or other flat form; and the following mixture prepared. Take of quick-lime two parts, and of litharge one part; temper them together to the consistence of a soft paste with soap-ley. Put this paste over all the parts of the horn, except such as are proper to be left transparent, in order to give it a nearer resemblance of the tortoise-shell. The horn must remain in this manner covered with the paste till it be thoroughly dry; when, the paste being brushed off, the horn will be found partly opaque and partly transparent, in the manner of tortoise-shell; and when put over a foil, of the kind of latten called *assidue*, will be scarcely distinguishable from it. It requires some degree of fancy and judgment to dispose of the paste in such a manner as to form a variety of transparent parts, of different magnitudes and figures, to look like the effect of nature: and it will be an improvement to add semitransparent parts; which may be done by mixing whitening with some of the paste to weaken its operation in particular places; by which spots of a reddish brown will be produced, which if properly interspersed, especially on the edges of the dark parts, will greatly increase both the beauty of the work, and its similitude with the real tortoise-shell.

HORN is also a sort of musical instrument of the wind kind; chiefly used in hunting, to animate and bring together the dogs and the hunters. The term anciently was, *wind a horn*, all horns being in those times compassed; but since straight horns are come in fashion, they say *blow a horn*, and sometimes *sound a horn*.—There are various lessons on a horn; as the recheat, double recheat, royal recheat, running or farewell recheat, &c. See RECHEAT.

The *French horn* is no other than a wreathed or contorted trumpet. It labours under the same defects as the trumpet itself; but these have of late been so palliated, as to require no particular selection of keys for this instrument. In the beginning of the year 1773, a foreigner, named Spandau, played in a concert at the opera-house a concerto, part whereof was in the key of C, with the minor-third; in the performance of which all the intervals seemed to be as perfect as in any wind-instrument. This improvement was effected by putting his right-hand into the bottom

Nº 157.

or bell of the instrument, and attempering the sounds by the application of his fingers to different parts of the tube.

The Hebrews made use of horns, formed of rams horns, to proclaim the jubilee; whence the name jubilee.

Cape Horn. See *Terra del Fuego*.

Horn-Beam, in botany. See CARPINUS.

Horn-Bill, in ornithology. See BUCEROS.

Horn-Blend, is a black or green indurated bole or clay, consisting of scaly particles, which are distinguishable from those of mica, by being less shining, thicker, and rectangular. It is generally found amongst iron ores, and sometimes intermixed with mica, forming a compact stone.

Human-Horns. In Dr Charles Leigh's natural history of Lancashire, Cheshire, and the Peak in Derbyshire, is the print of a woman with two horns on her head. When she was 28 years of age an excrescence grew upon her head like a wen, which continued 30 years, and then grew into two horns. After four years she cast them, and in their place grew two others. After four years she cast these also; and the horns which were on her head in 1668 (the time when the account was written) were then loose. Her picture and one of her horns are in Ashmole's museum. In the university library at Edinburgh is preserved a horn which was cut from the head of Elizabeth Love, in the 50th year of her age. It grew three inches above the ear, and was growing seven years.

Horn Distemper, a disease incident to horned cattle, affecting the internal substance of the horn commonly called the pith, which it insensibly wastes, and leaves the horn hollow. The pith is a spongy bone, the cells of which are filled with an unctuous matter. It is furnished with a great number of small blood vessels, is overspread with a thin membrane, and appears to be united by sutures with the bones of the head.—According to an account of this distemper, published by Dr Tofts in the Memoirs of the American Academy, vol. i. the said spongy bone is sometimes partly, and sometimes entirely, wasted. The horn loses its natural heat, and a degree of coldness is felt upon handling it. The distemper, however, is seldom suspected without a particular acquaintance with the other symptoms, which are a dulness in the countenance of the beast, a sluggishness in moving, a failure of appetite, an inclination to lie down, and, when accompanied with an inflammation of the brain, a giddiness and frequent tossing of the head. The limbs are sometimes affected with stiffness, as in a rheumatism; in cows the milk often fails, the udder is hard, and in almost all cases there is a sudden wasting of the flesh. As soon as the distemper is discovered, an opening into the diseased horn should be immediately made; which may be done with a gimlet of a moderate size, in such a part of the horn as is most favourable for the discharge. It is recommended as most prudent to bore at first two or three inches above the head. If it is found hollow, and the gimlet passes through to the opposite side, and no blood discharges from the aperture, it may be best to bore still lower, and as near the head as it shall be judged that the hollowness extends. This opening is affirmed to be a necessary measure, and often gives immediate relief. Care must be

Horn
||
Horners

be taken to keep it clear, as it is apt to be clogged by a thin fluid that gradually oozes out and fills up the passage. Some have practised sawing off the horn; but, according to the best observations, it does not succeed better than boring. From the cases Dr Tufts has seen, he is led to conclude that injections are in general unnecessary; that, when the distemper is early discovered, no more is required than a proper opening into the horn, keeping it sufficiently clear for the admission of fresh air, the removal of the compression, and the discharge of floating matter. But when the distemper has communicated its effects to the brain, so as to produce a high degree of inflammation, it is much to be doubted whether any method of cure will succeed.

HORN-Fish, Gar-fish, or Sea-Needle. See *Esox*.

HORN-Work, in fortification, an outwork composed of two demi-bastions joined by a curtain. See *FORTIFICATION*.

HORNBY, a town of Lancashire in England, seated on a branch of the river Lune, and beautified with a handsome parochial chapel. The ruins of a decayed castle are still to be seen here. W. Long. 2. 20. N. Lat. 54. 6.

HORN-CASTLE, a town of Lincolnshire in England. It had a castle, as the name imports; from the architecture of which, and the Roman coins that are sometimes dug up here, it is thought to have been a camp or station of the Romans. The town is well built, and is almost surrounded with water. It is a signiory of 13 lordships. In these lordships there are several chapels for the convenience of the inhabitants, who are at too great a distance from the mother-church, and pretty numerous. It has a market on Saturdays, and fairs in June and August.

HORNDON, a town of Essex, in England. It stands near a rivulet, that at a small distance from hence falls into the Thames, which is there called the *Hope*. E. Long. 0. 30. N. Lat. 51. 20.

HORNECK (Dr Anthony), a learned and pious divine, was born at Baccharach, in the Lower Palatinate, in 1641. He studied divinity under Dr Spanheim at Heidelberg; and afterwards coming to England, completed his studies at Oxford, and became vicar of Allhallows in that city. In 1665, he removed into the family of the duke of Albemarle; and was tutor to his grace's son, then lord Torrington. The duke presented him to the rectory of Doulton in Devonshire, and procured for him a prebend in Exeter. He was afterwards chosen preacher of the Savoy. In 1693, he was collated to a prebend in Westminster, and the same year admitted to a prebend in the cathedral of Wells. He published, 1. *The great law of consideration.* 2. *The happy ascetick.* 3. *Delight and judgment.* 4. *The fire of the altar.* 5. *The exercise of prayer.* 6. *The crucified Jesus.* 7. *Several sermons, and other works.* He died in 1696, and was interred in Westminster abbey, where a monument is erected to his memory.

HORNERS, those people whose business it is to prepare various utensils of the horns of cattle. The horners were a very ancient and considerable fraternity in the city of London some hundred years ago. In the reign of Edward II. they complained to parliament, that by foreigners buying up the horns in Eng-

land, they were in danger of being ruined, and this business lost to the nation. For this reason was made the statute 6 Edw. IV. by which the sale of horns to foreigners (except such as the said horners refused) was prohibited; and the wardens had power granted them to search all the markets in London and 24 miles round, and to inspect Sturbridge and Ely fairs, to prevent such practices, and to purchase horns at stated prices. But on plausible pretences this law was repealed in the reign of James I. and thereupon the old evil revived. The horners again applied to parliament, and king Edward's statute was renewed (excepting as to the inspection of the fairs), and still remains in force. The importation of unwrought horns into this country is also prohibited. In 1750, there were exported to Holland 514,500 lantern-leaves, besides powder flasks. There was formerly a duty of 20 shillings a thousand, under which in 1682 were exported 76,650; but in the reign of George I. this duty was taken off, and these and all other manufactures made of horns may be exported free. The present company of horners were incorporated January 12. 1638; and consist of a master, two wardens, and nine assistants, without livery or hall. They have a warehouse in Spitalfields, to which the horns are sent as brought from town and country markets, and thence regularly divided, the widows and orphans of deceased members having equal shares.

HORNET, in zoology, a species of wasp. See *VESPA*.

HORNING, in Scots law, a writing issuing from the signet, in his majesty's name, at the instance of a creditor against his debtor, commanding him to pay or perform within a certain time, under pain of being declared rebel, and by a caption put in prison.

HORNIUS (George), professor of history at Leyden, was born in the Palatinate, and died at Leyden in 1670. He was a little maniacal towards the end of his life; which disorder was supposed to be occasioned by the loss of 6000 florins he had entrusted with an alchemist at the Hague. His works are, 1. *Historia Ecclesiastica ad an.* 1666. This has been well esteemed. 2. *De Originibus Americanis*, 1652, 8vo. 3. *Geographia Velus & Nova.* 4. *Orbis Politicus.* He was a man of vast reading, rather than great parts.

HORNSEY, a town in Yorkshire, 188 miles from London. It is almost surrounded by a small arm of the sea; and the church having a high steeple, is a noted sea-mark. Not many years ago there was a street here called *Hornsey beck*, which was washed away by the sea, except a house or two. E. Long. 0. 6. N. Lat. 54. 0.

HORNSEY, a town of Middlesex, five miles north of London. It is a long straggling place, situated in a low valley, but extremely pleasant, having the new-river winding through it. Its church, of which Highgate is a hamlet, is supposed to be built with the stones that came from Lodge-Hill, the bishop of London's hunting-seat in his park here; it having been his manor from the most ancient times. About a mile nearer this is a coppice of young trees, called *Hornsey wood*, at the entrance of which is a public house, to which great numbers of persons resort from the city. This house being situated on the top of a hill, affords a delightful prospect of the neighbouring country.

HORNPIPE, a common instrument of music in

Hornet
||
Hornpipe.

Horologium,
Horoscope.

Wales, consisting of a wooden pipe, with holes at stated distances, and a horn at each end; the one to collect the wind blown into it by the mouth, and the other to carry off the sounds as modulated by the performer.

HORNPIPE is also the name of an English air, probably derived from the above instrument. The measure of this air is triple time, with six crotchets in a bar; four of which are to be beat with the hand down and two up.

HOROLOGIUM, *ὁρολογιον* (composed of *ωρα hora*, "time, hour," and *λογος* "speech, discourse"), a common name among ancient writers for any instrument or machine for measuring the hours; (see CHRONOMETER).—Such are our clocks, watches, sundials, &c. See CLOCK, WATCH, DIAL, and CLEPSYDRA.

Modern inventions, and gradual improvements, have given birth to some new terms that come properly under this head, and annexed new meanings to others totally different from what they had originally. All chronometers that announced the hour by striking on a bell, were called *clocks*: thus, we read of pocket-clocks, though nothing could seem more absurd than to suppose that a clock, according to the modern idea, should be carried in the pocket. In like manner, all clocks that did not strike the hour were called *watches* or *time-pieces*; and the different parts of a striking clock were distinguished by the watch-part and the clock-part; the former meaning that part which measures the time, and the latter the part which proclaims the hours. In the report of Sir Isaac Newton to the house of commons, *anno* 1713, relative to the longitude act, he states the difficulties of ascertaining the longitude by means of a watch; yet it is obvious, from several circumstances, that his remarks were directly to be understood of a time-piece regulated by a pendulum; for his objections are founded on the known properties of the pendulum, some of which differ essentially from the properties of the balance and spring. It is also to be remembered, that all the attempts of Huygens for finding the longitude were by means of pendulum clocks that did not strike the hour, and consequently, according to the language of the times, were called *watches*. At this time such machines for measuring time as are fixed in their place are called *clocks*, if they strike the hour: if they do not strike the hour, they are called *time-pieces*; and when constructed with more care, for a more accurate measure of time, they are called *regulators*. Some artists of late have affected to call such watches as were constructed for astronomical and nautical observations by the name of *time-pieces*, probably to intimate that they possess the advantages of those constructed with a pendulum.

Mr John Harrison first gave the name of *time-keeper* to his watch, for the performance of which he received from parliament the sum of £. 20,000. See LONGITUDE.

For the account of the principles of this machine, see TIME-KEEPER. And for the chief improvements that have been made for the more accurate measure of time, see PALLETS, PENDULUM, and SCAPEMENT.

HOROSCOPE, in astrology, the degree or point of the heavens rising above the eastern point of the horizon at any given time when a prediction is to be made of a future event: as, the fortune of a person

then born, the success of a design then laid, the weather, &c. The word is composed of *ωρα hora*, "hour," and the verb *σχιπτομαι*, *specio, considero*. "I consider." Horoscope

They were formerly so infatuated with horoscopes, that Albertus Magnus, Cardan, and others, are said to have had the temerity to draw that of Jesus Christ.

HOROSCOPE is also used for a scheme or figure of the twelve houses; i. e. the twelve signs of the zodiac, wherein is marked the disposition of the heavens for any given time. Thus we say, to draw a horoscope, construct a horoscope &c. We call it, more peculiarly, *calculating a nativity*, when the life and fortune of a person are the subject of the prediction; for they draw horoscopes of cities, great enterprizes, &c. See HOUSE.

HOROSCOPY. See DIVINATION, n° 2.

HORREA, in Roman antiquity, were public magazines of corn and salt meat, out of which the soldiers were furnished on their march in the military roads of the empire. *Horrea* was also the name which they gave to their granaries.

HORROX (Jeremiah), an eminent English astronomer in the 17th century, was born at Texteth near Liverpool in Lancashire in 1619. He died, to the great loss of that science and of the world, in the 23d year of his age, after he had just finished his *Venus in sole visa*; which, with some other works, were published by Dr Wallis, in quarto.

HORROR, strictly signifies such an excess of fear as makes a person tremble. See FEAR, FRIGHT, and TERROR. In medicine, it denotes a shivering and shaking of the whole body, coming by fits. It is common at the beginning of all fevers, but is particularly remarkable in those of the intermittent kind.

Horror of a Vacuum, was an imaginary principle among the ancient philosophers, to which they ascribed the ascent of water in pumps, and other similar phenomena, which are now known to be occasioned by the weight of the air.

HORSE, in zoology. See the article EQUUS.

Horses were very rare in Judæa till Solomon's time. Before him we find no horsemen mentioned in the armies of Israel. David having won a great battle against Hadadezer king of Shobah (2 Sam. viii. 4, 5), took 1700 horses, and lamed all belonging to the chariots of war, reserving only 100 chariots. The judges and princes of Israel used generally to ride on mules or asses. After David's time, horses were more common in the country of Judah, &c. Solomon is the first king of Judah who had a great number of horses, and he kept them rather for pomp than for war; for we do not read that he made any military expeditions. He had, says the scripture (1 Kings iv. 26.) 40,000 stalls of horses for his chariots, and 12,000 horsemen distributed in his fortified places (1 Kings x. 26.) He had his horses from Egypt (*ibid.* ver. 28, 29.); and there was not a set which did not cost him more than 600 shekels, which make of our money about 90l. Moses had forbidden the king of the Hebrews to keep a great number of horses (Deut. xvii. 16.), lest at any time he should be inclined to carry the people back into Egypt.

We read in the second book of Kings (xxiii. 17.), that Josiah took away the horses which the kings of Judah his predecessors had consecrated to the sun. We know

Horoscope
Horse.

Horse. know the sun was worshipped over all the east, and that the horse, the swiftest of tame beasts, was consecrated to this deity, who was represented as riding in a chariot drawn by the most beautiful and swiftest horses in the world, and performing every day his journey from east to west, in order to communicate his light to mankind. Xenophon describes a solemn sacrifice of horses, which was made with ceremony to the sun: they were all the finest steeds, and were led with a white chariot, crowned, and consecrated to the same god. We may believe that the horses which Josiah removed out of the court of the temple, were appointed for the like sacrifices. The rabbins inform us, that these horses were every morning put to the chariots dedicated to the sun, whereof there is mention made in the same book; and that the king, or some of his officers, got up and rode to meet the sun in its rising, as far as from the eastern gate of the temple to the suburbs of Jerusalem. Others are of opinion, that the horses mentioned in the book of kings were of wood, stone, or metal, erected in the temple in honour of the sun: Others, that they were horses which none were permitted to ride or fasten to the yoke, but were free, and left to themselves, like those which Julius Cæsar let loose and set at liberty after his passage of the Rubicon.

Horses were used both amongst the Greeks and Romans in war, but were not originally very numerous; for as each horseman provided his own horse, few would be able to bear the expence. Horses for a considerable time were managed by the voice alone, or by a switch, without bridle, saddle, or stirrups. Their harness was skins of beasts, or sometimes cloth. Both horses and men amongst the Greeks underwent a severe probation before their admission into the cavalry. —Horse-races were common amongst the Greeks and Romans, and the place where they ran or breathed their couriers was called *hippodromus*.

Management of a Horse upon and after a Journey. See that his shoes be not too strait, or press his feet, but be exactly shaped; and let him be shod some days before you begin a journey, that they may be settled to his feet.

Sportman's Dictionary. Observe that he is furnished with a bitt proper for him, and by no means too heavy, which may incline him to carry low, or to rest upon the hand when he grows weary, which horsemen call *making use of his fifth leg*.

The mouth of the bitt should rest upon his bars about half a finger's-breadth from his tusches, so as not to make him frumple his lips; the curb should rest in the hollow of his beard a little above the chin; and if it gall him, you must defend the place with a piece of buff or other soft leather.

Take notice that the saddle do not rest upon his withers, reins, or back-bone, and that one part of it do not press his back more than another.

Some riders gall a horse's sides below the saddle with their stirrup-leathers, especially if he be lean; to hinder it, you should fix a leather-strap between the points of the fore and hind-bows of the saddle, and make the stirrup-leather pass over them.

Begin your journey with short marches, especially if your horse has not been exercised for a long time: suffer him to stale as often as you find him inclined;

and not only so, but invite him to it: but do not excite your mares to stale, because their vigour will be thereby diminished.

It is advisable to ride very softly, for a quarter or half an hour before you arrive at the inn, that the horse not being too warm, nor out of breath, when put into the stable, you may unbridle him: but if your business obliges you to put on sharply, you must then (the weather being warm) let him be walked in a man's hand, that he may cool by degrees; otherwise, if it be very cold, let him be covered with cloths, and walked up and down in some place free from wind; but in case you have not the conveniency of a sheltered walk, stable him forthwith, and let his whole body be rubbed and dried with straw.

Although some people will have their horses legs rubbed down with straw as soon as they are brought into the stable, thinking to supple them by that means; yet it is one of the greatest errors that can be committed, and produces no other effects than to draw down into the legs those humours that are always stirred up by the fatigue of the journey: not that the rubbing of horses legs is to be disallowed; on the contrary, we highly approve of it, only would not have it done at their first arrival, but when they are perfectly cooled.

Being come to your inn, as soon as your horse is partly dried, and ceases to beat in the flanks, let him be unbridled, his bit washed, cleansed, and wiped, and let him eat his hay at pleasure.

If your horse be very dry, and you have not given him water on the road, give him oats washed in good mild ale.

The dust and sand will sometimes so dry the tongues and mouths of horses, that they lose their appetites: in such case, give them bran well moistened with water to cool and refresh their mouths; or wash their mouths and tongues with a wet sponge, to oblige them to eat.

The foregoing directions are to be observed after moderate riding; but if you have rode excessively hard, unsaddle your horse, and scrape off the sweat with a sweating-knife, or scraper, holding it with both hands, and going always with the hair; then rub his head and ears with a large hair-cloth, wipe him also between the fore-legs and hind-legs; in the mean while, his body should be rubbed all over with straw, especially under his belly and beneath the saddle, till he is thoroughly dry.

That done, set on the saddle again, cover him; and if you have a warm place, let him be gently led up and down in it, for a quarter of an hour; but if not, let him dry where he stands.

Or you may unsaddle him immediately; scrape off the sweat; let the ostler take a little vinegar in his mouth, and squirt it into the horse's; then rub his head, between the fore and hind-legs, and his whole body, till he is pretty dry: let him not drink till thoroughly cool and has eaten a few oats; for many, by drinking too soon, have been spoiled. Set the saddle in the sun or by a fire, in order to dry the panels.

When horses are arrived in an inn, a man should, before they are unbridled, lift up their feet, to see whether they want any of their shoes, or if those they

Horfe.

have do not rest upon their sides; afterwards he should pick and clear them of the earth and gravel, which may be got betwixt their shoes and soles.

If you water them abroad, upon their return from the river cause their feet to be stopped with cow-dung, which will ease the pain therein; and if it be in the evening, let the dung continue in their feet all night, to keep them soft and in good condition: but if your horse have brittle feet, it will be requisite to anoint the fore-feet, at the on-setting of the hoofs, with butter, oil, or hog's-grease, before you water him in the morning, and in dry weather they should be also greased at noon.

Many horses, as soon as unbridled, instead of eating, lay themselves down to rest, by reason of the great pain they have in their feet, so that a man is apt to think them sick: but if he looks to their eyes, he will see they are lively and good; and if he offers them meat as they are lying, they will eat it very willingly; yet if he handles their feet, he will find them extremely hot, which discovers their suffering in that part. You must therefore see if their shoes do not rest upon their soles, which is somewhat difficult to be certainly known without unshoeing them; but if you take off their shoes, then look to the inside of them, and you may perceive that those parts which rest upon the soles are more smooth and shining than the others: in this case you are to pare their feet in those parts, and fix on their shoes again, anointing the hoofs, and stopping the soles with scalding hot black pitch or tar.

After a long day's journey, at night feel your horse's back, if he be pinched, galled, or swelled (if you do not immediately discover it, perhaps you may after supper), there is nothing better than to rub it with good brandy and the white of an egg. If the galls are between the legs, use the same remedy; but if the ostler rubs him well between the legs, he will seldom be galled in that part.

In order to preserve horses after travel, take these few useful instructions. When you are arrived from a journey, immediately draw the two heel-nails of the fore-feet; and, if it be a large shoe, then four: two or three days after, you may blood him in the neck, and feed him for 10 or 12 days only with wet bran, without giving him any oats; but keep him well littered.

The reason why you are to draw the heel-nails, is because the heels are apt to swell, and if they are not thus eased, the shoes would press and straiten them too much: it is also advisable to stop them with cow-dung for a while; but do not take the shoes off, nor pare the feet, because the humours are drawn down by that means.

The following bath will be very serviceable for preserving your horse's legs. Take the dung of a cow or ox and make it thin with vinegar, so as to be of the consistence of thick broth; and having added a handful of small salt, rub his fore-legs from the knees, and the hind-legs from the gambrels, chafing them well with and against the hair, that the remedy may sink in and stick to those parts, that they may be all covered over with it. Thus leave the horse till morning, not wetting his legs, but giving him his water that evening in a pail: next morning lead him to the ri-

ver, or wash his legs in well-water, which is very good, and will keep them from swelling.

Those persons, who, to recover their horses feet, make a hole in them, which they fill with moistened cow-dung, and keep it in their fore-feet during the space of a month, do very ill; because, though the continual moisture that issues from the dung occasions the growing of the hoof, yet it dries and shrinks it so excessively when out of that place, that it splits and breaks like glass, and the foot immediately straitens. For it is certain, that cow-dung (contrary to the opinion of many people) spoils a horse's hoof: it does indeed moisten the sole; but it dries up the hoof, which is of a different nature from it. In order, therefore, to recover a horse's feet, instead of cow-dung, fill a hole with blue wet clay, and make him keep his fore-feet in it for a month.

Most horses that are fatigued, or over-rid, and made lean by long journeys, have their flanks altered without being purfy, especially vigorous horses that have worked too violently.

There is no better method to recover them, than to give each of them in the morning half a pound of honey very well mingled with scalded bran; and when they readily eat the half pound, give them the next time a whole one, and afterwards two pounds, every day continuing this course till your horses are empty, and purge kindly with it; but as soon as you perceive that their purging ceases, forbear to give them any more honey.

You may administer powder of liquorice in the scalded bran for a considerable time; and to cool their blood, it will not be improper to let them have three or four glisters.

In case the horse be very lean, it is expedient to give him some wet bran, over and above his proportion of oats; and grass is also extraordinary beneficial, if he be not purfy.

If it be a mare, put her to a horse; and if she never had a foal before, it will enlarge her belly.

Sometimes excessive feeding may do horses more harm than good, by rendering them subject to the farcy. You should therefore be cautious in giving them too great a quantity at a time, and take a little blood from them now and then.

When a horse begins to drink water heartily, it is a certain sign that he will recover in a short time. As to the method of giving him water during a journey, observe the following rules:

All the while you are upon a journey, let your horse drink of the first good water you come to, after seven o'clock in the morning if it be in summer-time, and after nine or ten in winter.

That is accounted good water which is neither too quick and piercing, nor too muddy and stinking.

This is to be done, unless you would have him gallop a long time after drinking; for if so, you must forbear.

Though it is the custom of England to run and gallop horses after drinking, which we call *watering-courses*, to bring them (as they say) into wind; yet, says M. de Solleysel, it is the most pernicious practice that can be imagined for horses, by which many are rendered purfy.

While a horse is drinking, draw up his head five or six times, making him move a little between every draught;

Horfe.

Horse. draught; and notwithstanding he be warm, and sweat very much, yet if he is not quite out of breath, and you have still four or five miles to ride, he will be better after drinking a little, than if he had drank none at all: it is true, indeed, that if the horse is very warm, you should, at coming out of the water, redouble your pace, to make him go at a gentle trot, to warm the water in his belly.

You ought to let him drink after this manner during the whole time of your journey; because, if when you happen to bait he be hot or sweaty, you must not let him drink for a long time, as it would endanger his life; and when his bridle is taken off, his excessive thirst will hinder him from eating, so that he will not offer to touch his meat for an hour or two, which perhaps your occasions will not allow you for a baiting time, and not to have any food will render him unfit for travel.

If you meet with any ford before you come to your inn, ride the horse through it two or three times, but not up to his belly: this will only cleanse his legs; but the coldness of the water will bind up the humours, and prevent them from descending.

If your horse has been very warm, and you have not had the conveniency of watering him upon the road, he will, when unbridled, eat but very little; therefore he should have his oats given him washed in ale or beer, or only some of them, if you intend to feed him again after he has drank.

Some are of opinion, that horses are often spoiled by giving them oats before their water; because they say the water makes the oats pass too soon, and out of the stomach undigested. But M. de Solleyfel affirms, that though it be the common custom not to do it till after, yet it is proper to feed with oats both before and after, especially if the horse be warm, and has been hard rode; for they will be a great deal the better for it, and in no danger of becoming sick.

*Buffon's
Nat. Hist.*

Breeding of Horses. When the stallion is chosen, and all the mares intended for him are collected together, there must be another stone-horse, to discover which of the mares are in heat; and, at the same time, contribute to inflame them. All the mares are to be brought successively to this stone-horse; which should also be inflamed, and suffered frequently to neigh. As he is for leaping every one, such as are not in heat keep him off, whilst those which are so suffer him to approach them. But instead of being allowed to satisfy his impulse, he must be led away, and the real stallion substituted in his stead. This trial is necessary for ascertaining the true time of the mare's heat, especially of those which have not yet had a colt; for with regard to such as have recently foaled, the heat usually begins nine days after their delivery; and on that very day they may be led to the stallion to be covered; and nine days after, by the experiment above mentioned, it may be known whether they are still in heat. If they are, they must be covered a second time; and thus successively every ninth day while their heat continues: for when they are impregnated, their heat abates, and in a few days ceases entirely.

But that every thing may be done easily and conveniently, and at the same time with success and advantage, great attention, expence, and precaution are requisite. The stud must be fixed in a good soil,

and in a suitable place, proportioned to the number of mares and stallions intended to be used. This spot must be divided into several parts, inclosed with rails or ditches well fenced; in the part where the pasture is the richest, the mares in fold, and those with colts by their sides, are to be kept. Those which are not impregnated, or have not yet been covered, are to be separated, and kept with the fillies in another close, where the pasture is less rich, that they may not grow too fat, which would obstruct the progress of generation. Lastly, the young stone colts or geldings, are to be kept in the driest part of the fields, and where the ground is most unequal; that by running over the uneven surface, they may acquire a freedom in the motion of their legs and shoulders. This close, where the stone colts are kept, must be very carefully separated from the others, lest the young horses break their bounds, and enervate themselves with the mares. If the tract be so large as to allow of dividing each of these closes into two parts, for putting oxen and horses into them alternately, the pasture will last much longer than if continually eaten by horses; the ox improving the fertility, whereas the horse lessens it. In each of these closes should be a pond; standing water being better than running, which often gripes them: and if there are any trees in the ground, they should be left standing, their shade being very agreeable to the horses in great heats; but all stems or stumps should be grubbed up, and all holes levelled, to prevent accidents. In these pastures your horses should feed during the summer; but in the winter the mares should be kept in the stable and fed with hay. The colts also must be housed, and never suffered to feed abroad in winter, except in very fine weather. Stallions that stand in the stable should be fed more with straw than hay; and moderately exercised till covering time, which generally lasts from the beginning of April to the end of June. But during this season they should have no other exercise, and be plentifully fed, but with the same food as usual. Before the stallion is brought to the mare, he should be dressed, as that will greatly increase his ardour. The mare must also be curried, and have no shoes on her hind feet, some of them being ticklish, and will kick the stallion. A person holds the mare by the halter, and two others lead the stallion by long reins; when he is in a proper situation, another assistant carefully directs the yard, pulling aside the mare's tail, as a single hair might hurt him dangerously. It sometimes happens that the stallion does not complete the work of generation, coming from the mare without making any injection: it should therefore be attentively observed, whether, in the last moments of the copulation, the dock of the stallions tail has a vibrating motion; for such a motion always accompanies the emission of the seminal lymph. If he has performed the act, he must on no consideration be suffered to repeat it; but be led away directly to the stable, and there kept two days. For, however able a good stallion may be of covering every day during the three months, it is much better to let him be led to a mare only every other day: his produce will be greater, and he himself less exhausted. During the first seven days, let four different mares be successively brought to him; and the ninth day let the first be again brought, and so successively while they continue in heat: but as

soon

Horse.

soon as the heat of any one is over, a fresh mare is to be put in her place, and covered in her turn every nine days; and as several retain even at the first, second, or third time, it is computed that a stallion, by such management, may, during the three months, cover 15 or 18 mares, and beget 10 or 12 colts. These animals have a very large quantity of the seminal lymph; so that a considerable portion of it is shed during the emission. In the mares likewise is an emission, or rather distillation of the seminal lymph, during the whole time they are horsing; ejecting a viscid whitish lymph, called the *beats*, which cease on conception. This ichor the Greeks called *hippomanes*; and pretended that philtres might be made of it, one remarkable effect of which was, to render a horse frantic with lust. This *hippomanes* is very different from that found in the secundines of the foal, which M. Daubenton first discovered, and has so accurately described its nature, origin, and situation. The ejection of this liquor is the most certain sign of the mare's heat; but it is also known by the inflation of the lower part of the vulva, by her frequent neighings, and attempts to get to the horses. After being covered, nothing more is requisite than to lead her away to the field. The first foal of a mare is never so strongly formed as the succeeding; so that care should be taken to procure for her, the first time, a larger stallion, that the defect of the growth may be compensated by the largeness of the size. Particular regard should also be had to the difference or congruity of the fashion of the stallion and the mare, in order to correct the faults of the one by the perfections of the other: especially never to make any disproportionate copulations, as of a small horse with a large mare, or a large horse with a small mare; as the produce of such copulation would be small, or badly proportioned. It is by gradations that we must endeavour to arrive at natural beauty: for instance, to give to a mare a little too clumsy, a well-made horse and finely shaped; to a small mare, a horse a little higher; to a mare which is faulty in her forehead, a horse with an elegant head and noble chest, &c.

It has been observed, that horses fed in dry and light grounds, produce temperate, swift, and vigorous foals, with muscular legs and a hard hoof; while the same bred in marshes and moist pastures have produced foals with a large heavy head, a thick carcase, clumsy legs, bad hoofs, and broad feet. These differences proceed from the air and food, which is easily understood; but what is more difficult to be accounted for, and still more essential than what we have hitherto observed, is, to be continually crossing the breed to prevent a degeneracy.

In coupling of horses, the colour and size should be suited to each other, the shape contrasted, and the breed crossed by an opposition of climates: but horses and mares foaled in the same stud should never be joined. These are essential articles; but there are others which should by no means be neglected: as that no short-docked mares be suffered in a stud, because from their being unable to keep off the flies, they are much more tormented by them than others which have a long sweeping tail; and their continual agitations from the stings of these insects, occasions a diminution in the quantity

of their milk, and has a great influence on the constitution and size of the colt, which will be vigorous in proportion as its dam is a good nurse. Care must also be taken, that the stud mares be such as have been always brought up in pastures, and never over-worked. Mares which have always been brought up in the stable on dry food, and afterwards turned to grass, do not breed at first: some time is required for accustoming them to this new aliment.

Though the usual season for the heat of mares be from the beginning of April to the end of June, yet it is not uncommon to find some among a large number that are in heat before that time: but it is advisable to let this heat pass over without giving them to the stallion, because they would foal in winter; and the colts, besides the inclemency of the season, would have bad milk for their nourishment. Again, if the mares are not in heat till after the end of June, they should not be covered that season; because the colts being foaled in summer, have not time for acquiring strength sufficient to repel the injuries of the following winter.

Many, instead of bringing the stallion to the mare, turn him loose into the close, where all the mares are brought together; and there leave him to choose such as will stand to him. This is a very advantageous method for the mares: they will always take horse more certainly than in the other; but the stallion, in six weeks, will do himself more damage than in several years by moderate exercise, conducted in the manner we have already mentioned.

When the mares are pregnant, and their belly begins to swell, they must be separated from those that are not, lest they hurt them. They usually go 11 months and some days; and foal standing, whereas most other quadrupeds lie down. Those that cannot foal without great difficulty, must be assisted; the foal must be placed in a proper situation; and sometimes, if dead, drawn out with cords. The head of the colt usually presents itself first, as in all other animals: at its coming out of the matrix, it breaks the secundines or integuments that inclose it, which is accompanied with a great flux of the lymph contained in them; and at the same time one or more solid lumps are discharged, formed by the sediment of the inspissated liquor of the allantoides. This lump, which the ancients called the *hippomanes of the colt*, is so far from being, as they imagined, a mass of flesh adhering to the head of the colt, that it is separated from it by a membrane called *amniois*. As soon as the colt is fallen, the mare licks it, but without touching the *hippomanes*; which points out another error of the ancients, who affirmed that she instantly devours it.

The general custom is to have a mare covered nine days after her foaling, that no time may be lost; but it is certain, that the mare having, by this means, both her present and future foal to nourish, her ability is divided, and she cannot supply both so largely as she might one only. It would therefore be better, in order to have excellent horses, to let the mares be covered only every other year; they would last the longer, and bring foals more certainly: for, in common studs, it is so far from being true that all mares which have been covered bring colts every year, that it is considered

Horse.

Horse. as a fortunate circumstance if half or at most two thirds of them foal.

Mares, when pregnant, will admit of copulation; but it is never attended with any superfoetation. They usually breed till they are 14 or 15 years of age; and the most vigorous till they are above 18. Stallions, when well managed, will engender till the age of 20, and even beyond; but it must be observed, that such horses as are soonest made stallions, are also the soonest incapable of generation: thus the large horses, which acquire strength sooner than the slender, and are therefore often used as stallions as soon as they are four years old, are incapable of generation before they are sixteen.

Gelding of HORSES. See GELDING.

Rearing of HORSES. See COLT.

Draught-HORSE, in farming, a sort of coarse-made horse destined for the service of the cart or plough. In the choice of these horses for what is called the *slow draught*, they are to be chosen of an ordinary height; for otherwise, when put into the cart, one draws unequally with the other. The draught-horse should be large bodied and strong loined, and of such a disposition, as rather to be too dull than too brisk, and rather to crave the whip than to draw more than is needful. Mares are the fittest for this use for the farmer, as they will be kept cheap, and not only do the work, but be kept breeding, and give a yearly increase of a foal. They should have a good head, neck, breast, and shoulders; for the rest of the shape, it is not of much consequence. Only, for breeding, the mare should have a large belly; for the more room a foal has in the dam, the better proportioned it will be. Draught-horses should be always kept to that employ. Some put them to the saddle on occasion, but it does them great harm, alters their pace, and spoils them for labour. The draught horse ought to have a large broad head, because horses of this shaped head are less subject than others to diseases of the eyes. The ears should be small, straight and upright; the nostrils large and open, that he may breathe with the more freedom. A horse with a full and bold eye always promises well. On the other hand, a sunk eye and an elevated brow are bad signs. The horse is esteemed fittest for this purpose also, that has a large and round buttock, which neither sinks down nor cuts. He must have a firm and strong tail, and the dock must be thick and well furnished with hair, and placed neither very high nor very low. The legs should be rather flat and broad than round; the roundness of the leg being a fault in a horse destined to labour that will soon ruin him. As to the hinder legs, the thighs should be fleshy and long, and the whole muscle which shows itself on the outside of the thigh should be large and very thick. No country can bring a parallel to the size and strength of our horses destined for the draught. In London there are instances of single horses that are able to draw on a plain, for a small space, the weight of three tons, and which can with ease, and for continuance, draw half that weight. The pack horses of Yorkshire usually carry a burden of 420 lb. over the highest hills of the north, as well as the most level roads: but the most remarkable proof of the strength of our British horses is derived from that of our mill horses; some of which will at one load carry 13 measures, which at

a moderate computation of 70 lb. each, will amount to 910 lb. Nothing is so essential to the health of these serviceable creatures as cleanliness; if they are fed ever so well, and not kept clean, they will be subject to numerous diseases.

The servant who has the care of them ought to be up very early, and to clean the racks and mangers from all filth. The currying of them ought to be carefully performed every morning, but not in the stable, for the dust to fall upon the other horses, as it is too often done. After the horses are dusted, they should daily twist a whisp of straw hard up, and wetting it in water, rub the legs, shoulders and body with it. Many of the diseases of draught-horses, which are not owing to nastiness, are owing to bad water; such as are two raw, too muddy, or too cold, being all improper. If there be any running stream in the neighbourhood, they should always be led to that to water every day in summer, but in winter, well-water is warmish, and is better for them. If there be a necessity of giving them well-water in summer, it must be drawn up some hours before the time, and exposed to the sun-beams in tubs or troughs; marsh-water or that of lowland ditches is worst of all. When the labouring horse has drank his water, he should have his oats given him, and these should be carefully sifted, and the manger dusted first. It is a common practice, as soon as a horse is come in from his work, to rub down his legs with a hard whisp of hay; but the best judges of horses absolutely condemn this, and observe, that this rubbing of the legs after hard labour brings down humours into them, and makes them stiff.

The rubbing itself is wholesome, but the doing it when the creature is hot is the mischief; while a horse is in a sweat it is a great relief and refreshment to him to have his body rubbed down, but when he is cold is the proper time to rub his legs. The racks are to be well supplied with hay, and the horses should be left to rest and eat, about two hours, and then led to water; after this their oats should be given them, and they should then go to work again.

In the evening, when the labour of the day is over, the first thing to be done is to examine the feet, and see if any thing is amiss about the shoes, and what earth or gravel is lodged in the foot, between the shoe and the sole, is to be picked out and some fresh cow-dung put in its place, which will cool and refresh the part.

A very material thing for the preservation of all sorts of cattle, but of none so much as draught-horses, is fresh and clean litter.

HORSE-Chestnut. See *ÆSCULUS*, and *HIPPOCASTANUM*.

be totally closed up, or the cranium in that part not be so hard as the rest for some years after. This openness is found to be increased upon the child's catching cold. When the disease continues long, it is reputed a sign of weakness and short life. In this case, it is usual to rub the head now and then with warm rum or brandy, mixed with the white of an egg and palm-oil. Sometimes the disorder arises from a collection of waters in the head called an *hydrocephalus*.

Stone-Horse. See STALLION.

Horse Tail. See EQUISETUM and EPHEDRA.

Horse-Vetch. See HIPPOCREPIS.

War-Horse. The proper rules for choosing a horse for service in war, are these: he should be tall in stature, with a comely head, and out-swelling forehead. His eye should be bright and sparkling, and the white part of it covered by the eye brow. The ears should be small, thin, short, and pricking; or if long, they should be moveable with ease, and well carried. The neck should be deep, and the breast large and swelling. The ribs bending, the chine broad and straight, and the buttocks round and full. The tail should be high and broad, neither too thick nor too thin; the thigh swelling; the leg broad and flat, and the pastern short. When such a horse is chosen, he must be kept high during the time of his teaching, that he may be full of vigour. His food must be sweet hay, and good clean oats, or two parts of oats and one part of beans or pease, well dried and hardened. The quantity should be half a peck in the morning, and the same quantity at noon and in the evening. Upon his resting days he is to be dressed between five and six in the morning, and watered at seven or eight. In the evening he is to be dressed at four, and watered about five, and he must always have provender given him after watering; he must be littered about eight, and then must have food given him for all night. The night before he is ridden all his hay is to be taken away about nine o'clock, and he must have a handful or two of oats about four in the morning: when he has eaten these, he is to be turned upon the snaffle, and rubbed very well with dry cloths; then saddled, and made fit for his exercise. When he has performed this, he is to be brought sweating into the stable, and rubbed down with dry wisps. When this has been done, the saddle is to be taken off, and he is to be rubbed down with dry cloths; the housing cloth is then to be laid on; and the saddle being again laid on, he is to be walked gently about till thoroughly cool. After this, he must stand without meat two or three hours, then he must be fed; and in the afternoon he is to be rubbed and dressed as before, and watered in the usual manner.

Horse Worm, in natural history, a species of fly-worm called also *bott*, produced of eggs deposited by a two-winged fly of the shape and size of the humble bee in the intestines of horses. See BOTTS.

River-Horse, in zoology. See HIPPOPOTAMUS.

HORSE is also used in the military language, to express the cavalry; or the body of soldiers who serve on horseback.

The horse includes horse guards, horse grenadiers, and troopers. Dragoons are also frequently comprehended under this name, though they fight on foot: of these there are now 18 regiments; besides three regiments of dragoon-guards raised in 1685. See GRADUATED, DRAGOONS, and GUARDS.

Master of the Horse. See MASTER.

Light-Horse, are regiments of cavalry, mounted on light swift horses, whose men are small and lightly accoutred. They were first raised in 1757. The denomination arose hence, that anciently they were lightly armed, in comparison of the royal guards, which were armed at all points.

Hungarian Horse. See HUSSARS.

HORSE is also a term used in various arts and manufactories, for something that helps to sustain their work from the ground, for the more commodious working at it.

The horse used by tanners and skinners, also called the *leg*, is a piece of wood cut hollow and roundish, four or five feet long, and placed aslope; upon which they pare their skins to get off the dirt, hair, flesh, &c.

HORSE is also used in carpentry, for a piece of wood jointed across two other perpendicular ones, to sustain the boards, planks, &c. which make bridges over small rivers; and on divers other occasions.

HORSE, in sea language, is the name of a rope reaching from the middle of a yard to its extremity, or what is called the *yard-arm*, and depending about two or three feet under the yard, for the sailors to tread upon whilst they are loosing, reefing, or furling the sails, rigging out the fludding-sail booms, &c. In order, therefore, to keep the horse more parallel to the yard, it is usually suspended to it at proper distances, by certain ropes called stirrups, which hang about two feet under the yard, having an eye in their lower ends through which the horse passes.

HORSE is also a thick rope, extended in a perpendicular direction near the fore or after-side of a mast, for the purpose of hoisting or extending some sail upon it. When it is fixed before a mast, it is calculated for the use of a sail called the *square-sail*, whose yard being attached to the horse, by means of a traveller or bull's eye, which slides up and down occasionally, is retained in a steady position; either when the sail is set, or whilst it is hoisting or lowering. When the horse is placed abaft or behind a mast, it is intended for the try-sail of a snow, and is accordingly very rarely fixed in this position, except in those sloops of war which occasionally assume the form of snows, in order to deceive the enemy.

HORSE is also a cant name introduced into the management of lotteries, for the chance or benefit of a ticket or number for one or more days, upon condition, if it be drawn a prize within the time covenanted for, of returning to the seller an undrawn ticket.—To determine the value of a horse; multiply the amount of the prizes in the lottery by the time the horse is hired for; and from the product subtract the amount of the number of prizes by the value of an undrawn ticket into the time of the horse: the remainder being divided by the number of tickets into the whole time of drawing, the quotient is the value of the horse. See LOTTERY.

Horse-Bread. See BREAD.

Horse-Dung, in gardening, is of great use in making hot-beds, for the raising all sorts of early crops; as fallading, cucumbers, melons, asparagus, &c. for which

Horse. which purposes no other kinds of dung will do so well. Horse dung ferments the strongest; and if mixed with litter and sea-coal ashes in a due proportion, will continue its heat much longer than any other sort of dung whatsoever: and afterward, when rotted, becomes an excellent manure for most sorts of land; more especially for such as are of a cold nature. For stiff clayey land, horse dung mixed with sea-coal ashes, and the cleansing of streets, will cause the parts to separate much sooner than any other compost: so that where it can be obtained in plenty, it is always to be recommended for such lands. See DUNG.

Horse. *Animated Horse-Hairs*, a term used to express a sort of long and slender water-worm, of a blackish colour, and so much resembling a horse-hair, that it is generally by the vulgar supposed to be the hair fallen from a horse's mane into the water as he drinks, and there animated by some strange power. Dr Lister has at large confuted this absurd opinion in the Philosophical Transactions.

Horse-Hair Worms. See AMPHIBIENA.

Horse-Hoeing Husbandry. See AGRICULTURE, n° 218.

Breaking of Horses. SECT. I. *The Method of preparing Horses to be mounted.*

THOUGH all horses are generally bought at an age when they have already been backed, they should be begun and prepared for the rider with the same care, gentleness, and caution, as if they had never been handled or backed, in order to prevent accidents, which might else arise from skittishness or other causes: and as it is proper that they should be taught the figure of the ground they are to go upon when they are at first mounted, they should be previously trotted in a *longe* on circles, without any one upon them.

Earl of Pembroke's Directions. The manner of doing this is as follows: Put an easy *cavesson* upon the horse's nose, and make him go forwards round you, standing quiet and holding the *longe*; and let another man, if you find it necessary, follow him with a whip. All this must be done very gently, and but a little at a time: for more horses are spoiled by overmuch work, than by any other treatment whatever; and that by very contrary effects; for sometimes it drives them into vice, madness, and despair, and often stupifies and totally dispirits them.

The first obedience required in a horse is going forwards; till he perform this duty freely, never even think of making him rein back, which would inevitably make him restive: as soon as he goes forwards readily, stop and caress him. You must remember in this, and likewise in every other exercise, to use him to go equally well to the right and left; and when he obeys, caress him and dismiss him immediately. If a horse that is very young takes fright and stands still, lead on another horse before him, which probably will induce him instantly to follow. Put a snaffle in his mouth; and when he goes freely, saddle him, girthing him at first very loose. Let the cord, which you hold, be long and loose; but not so much so as to endanger the horse's entangling his legs in it. It must be observed, that small circles, in the beginning, would constrain the horse too much, and put him upon defending himself. No bend must be required at first: never suffer him to gallop false; but whenever he attempts it, stop him without delay, and then set him off afresh. If he gallops of his own accord, and true, permit him to continue it; but if he does it not volun-

tarily, do not demand it of him at first. Should he fly and jump, shake the cord gently upon his nose without jerking it, and he will fall into his trot again. If he stands still, plunges, or rears, let the man who holds the whip make a noise with it; but never touch him till it be absolutely necessary to make him go on. When you change hands, stop and caress him, and entice him by fair means to come up to you: for by presenting yourself, as some do, on a sudden before horses, and frightening them to the other side, you run a great risk of giving them a shyness. If he keeps his head too low, shake the *cavesson* to make him raise it; and in whatever the horse does, whether he walks, trots, or gallops, let it be a constant rule, that the motion be determined, and really such as is intended, without the least shuffling, pacing, or any other irregular gait.

Of placing the Rider.

SECT. II *The Method of placing the Rider and rendering him firm on Horseback, with some occasional Instructions for Riders and the Horses.*

It is necessary that the greatest attention, and the same gentleness that is used in teaching the horses, be observed likewise in teaching the rider, especially at the beginning. Every method and art must be practised to create and preserve, both in man and horse, all possible feeling and sensibility; contrary to the usage of most riding-masters, who seem industriously to labour at abolishing these principles both in the one and the other. As so many essential points depend upon the manner in which a man is at first placed on horseback, it ought to be considered and attended to with the strictest care and exactness.

The absurdity of putting a man, who perhaps has never before been upon a horse, on a rough trotting horse, on which he is obliged to stick with all the force of his arms and legs, is too obvious to need mentioning. This rough work, all at once, is plainly as detrimental at first, as it is excellent afterwards in proper time. No man can be either well or firmly seated on horseback, unless he be master of the balance of his body, quite unconstrained, with a full possession of himself, and at his ease; none of which requisites can he enjoy, if his attention be otherwise engaged; as it must wholly be in a raw, unsupplied, and un-

Of placing
the Rider.

prepared lad, who is put at once upon a rough horse; in such a distressful state, he is forced to keep himself on at any rate, by holding to the bridle (at the expense of the sensibility both of his own hand and the horse's mouth), and by clinging with his legs, in danger of his life, and to the certain depravation of a right feeling in the horse.

The first time a man is put on horseback, it ought to be upon a very gentle one. He never should be made to trot, till he is quite easy in the walk; nor gallop, till he is able to trot properly. The same must be observed in regard to horses; they should never be made to trot till they are obedient, and their mouths are well formed on a walk, nor be made to gallop, till the same be effected on a trot. When he is arrived at such a degree of firmness in his seat, the more he trots, and the more he rides rough horses, the better. This is not only the best method, but also the easiest and the shortest: by it a man is soon made sufficiently an horseman for a soldier: but by the other detestable methods that are commonly used, a man, instead of improving, contracts all sorts of bad habits, and rides worse and worse every day; the horse too becomes daily more and more unfit for use. In proceeding according to the manner proposed, a man is rendered firm and easy upon the horse, both his own and the horse's sensibility is preserved, and each in a situation fit to receive and practise all lessons effectually.

Among the various methods that are used of placing people on horseback, few are directed by reason. Before you let the man mount, teach him to know, and always to examine, if the curb be well placed, (that is, when the horse has a bit in his mouth, which at first he should not; but only a snaffle, till the rider is firm in his seat, and the horse also somewhat taught); likewise to know if the nose-band be properly tight; the throat-band loose; and the mouth-piece neither too high nor too low in the horse's mouth, but rightly put so as not to wrinkle the skin nor to hang lax; the girths drawn moderately, but not too tight; and the crupper and the breast-plate properly adjusted. A very good and careful hand may venture on a bit at first, and succeed with it full as well as by beginning with a snaffle alone; only colts, indeed, it is better, in all schools whatsoever, to avoid any pressure on the bars just at first, which a curb, though ever so delicately used, must in some degree occasion. When the bridle, &c. have been well looked to, let the man approach the horse gently near the shoulder; then taking the reins and an handful of the mane in his left hand, let him put his foot softly in the left stirrup, by pulling it towards him, lest he touch the horse with his toe; then raising himself up, let him rest a moment on it with his body upright, but not stiff; and after that, passing his right leg clear over the saddle without rubbing against any thing, let him seat himself gently down. He must be cautious not to take the reins too short, for fear of making the horse rear, run, or fall back, or throw up his head; but let him hold them of an equal length, neither tight nor slack, and with the little finger betwixt them. It is fit that horses should be accustomed to stand still to be mounted, and not to stir till the rider pleases. All soldiers should be in-

structed to mount and dismount equally well on both sides, which may be of great use in times of hurry and confusion. Then place the man in his saddle, with his body rather back, and his head held up with ease, without stiffness; seated neither forwards, nor very backwards; with the breast pushed out a little, and the lower part of the body likewise a little forwards; the thighs and legs turned in without constraint, and the feet in a straight line, neither turned in nor out. By this position, the natural weight of the thighs has a proper and sufficient pressure of itself, and the legs are in readiness to act when called upon: they must hang down easy and naturally; and be so placed, as not to be wriggling about, touching, and tickling, the horse's sides, but always near them in case they should be wanted, as well as the heels.

The body must be carefully kept easy and firm, and without any rocking when in motion; which is a bad habit very easily contracted, especially in galloping. The left elbow must be gently leant against the body, a little forwards: unless it be so rested, the hand cannot be steady, but will always be checking, and consequently have pernicious effects on the horse's mouth. And the hand ought to be of equal height with the elbow; if it were lower, it would constrain and confine the motion of the horse's shoulders: but, as the mouths of horses are different, the place of the hand also must occasionally differ: a leaning, low, heavy, fore-hand, requires a high hand; and a horse that pokes out his nose, a low one. The right-hand arm must be placed in symmetry with the left; only let the right hand be a little forwarder or backwarder, higher or lower, as occasions may require, in order that both hands may be free; both arms must be a little bent at the elbow, to prevent stiffness.

A soldier's right hand should be kept unemployed in riding; it carries the sword, which is a sufficient business for it.

There remains one farther observation, that ought not to be omitted, about the hand, that it must be kept clear of the body; *i. e.* about two inches and a half forwards from it, with the nails turned opposite to the belly, and the wrist a little rounded with ease; a position not less graceful than ready for slackening, tightening, and moving the reins from one side to the other, as may be found necessary.

When the men are well placed, the more rough trotting they have without stirrups the better; but with a strict care always, that their position be preserved very exactly. In all cases, great care must be taken to hinder their clinging with their legs: in short, no sticking by hands or legs is ever to be allowed of at any time. If the motion of the horse be too rough, slacken it, till the rider grows by degrees more firm; and when he is quite firm and easy on his horse in every kind of motion, stirrups may be given him; but he must never leave off trotting often without any.

The stirrups must be neither short nor long; but of such a length, that when the rider, being well placed, puts his feet into them (about one third of the length of each foot from the point of it), the points may be between two and three inches higher than the heels. The rider must not bear upon his stirrups, but only

Of placing
the Rider.

Instructions
concerning
both Man
and Horse.

let the natural weight of his legs rest on them: For if he bears upon them he would be raised above and out of his saddle; which should never be, except in charging sword in hand, with the body inclined forwards at the very instant of attacking. Spurs may be given as soon as the rider is grown familiar with stirrups; or even long before, if his legs are well placed.

A hand should always be firm, but delicate: a horse's mouth should never be surprised by any sudden transition of it, either from slack to tight, or from tight to slack. Every thing in horsemanship must be effected by degrees, but at the same time with spirit and resolution. That hand which, by giving and taking properly, gains its point with the least force, is the best; and the horse's mouth, under this same hand's directions, will also consequently be the best, supposing equal advantages in both from nature. This principle of gentleness should be observed upon all occasions in every branch of horsemanship. Sometimes the right hand may be necessary, upon some troublesome horses, to assist the left: but the seldomer this is done, the better; especially in a soldier, who has a sword to carry, and to make use of.

The snaffle must on all occasions be uppermost; that is to say, the reins of it must be above those of the bridle, whether the snaffle or the bit be used separately, or whether they be both used together. When the rider knows enough, and the horse is sufficiently prepared and settled to begin any work towards suppling, one rein must be shortened according to the side worked to; but it must never be so much shortened, as to make the whole strength rest on that rein alone: for, not to mention that the work would be false and bad, one side of the horse's mouth would by that means be always deadened; whereas, on the contrary, it should always be kept fresh by its own play, and by the help of the opposite rein's acting delicately in a somewhat smaller degree of tension; the joint effect of which produces in a horse's mouth the proper, gentle, and easy, degree of *appui* or bearing.

A coward and a madman make alike bad riders, and are both alike discovered and confounded by the superior sense of the creature they are mounted upon, who is equally spoiled by both, though in very different ways. The coward, by suffering the animal to have his own way, not only confirms him in his bad habits, but creates new ones in him: and the madman, by false and violent motions and corrections, drives the horse, through despair, into every bad and vicious trick that rage can suggest.

It is very requisite in horsemanship, that the hand and legs should act in correspondence with each other in every thing; the latter always subservient and assistant to the former. Upon circles, in walking, trotting, or galloping, the outward leg is the only one to be used, and that only for a moment at a time, in order to set off the horse true, or put him right if he be false; and as soon as that is done, it must be taken away again immediately: but if the horse be lazy, or otherwise retains himself, both legs must be used and pressed to his sides at the same time together. The less the legs are used in general, the better. Very delicate

Instructions
concerning
both Man
and Horse.

good riders, with horses they have dressed themselves, will scarcely ever want their help. By the term *outward* is understood the side which is more remote from the centre; and by *inward* is meant the side next to the centre. In reining back, the rider should be careful not to use his legs, unless the horse backeth on his shoulders; in which case they must be both applied gently at the same time, and correspond with the hand. If the horse refuse to back at all, the rider's legs must be gently approached, till the horse lifts up a leg, as if to go forwards; at which time, when that leg is in the air, the rein of the same side with that leg which is lifted up, will easily bring that same leg backwards; and accordingly oblige the horse to back; but if the horse offers to rear, the legs must be instantly removed away. The inward rein must be tighter on circles, so that the horse may bend and look inwards; and the outward one crossed over a little towards it; and both held in the left hand.

Let the man and horse begin on very slow motions, that they may have time to understand and reflect on what is taught them; and in proportion as the effects of the reins are better comprehended, and the manner of working becomes more familiar, the quickness of motion must be increased. Every rider must learn to feel, without the help of the eye, when a horse goes false, and remedy the fault accordingly: this is an intelligence, which nothing but practice, application, and attention, can give, in the beginning on slow motions. A horse may not only gallop false, but also trot and walk false. If a horse gallops false, that is to say, if going to the right he leads with the left leg, or if going to the left he leads with the right; or in case he is disunited, *i. e.* if he leads with the opposite leg behind to that which he leads with before; stop him immediately, and put him off again properly. The method of effecting this, is by approaching your outward leg, and putting your hand outwards; still keeping the inward rein the shorter, and the horse's head inwards, if possible: and if he should still resist, then bend and pull his head outwards also; but replace it again, bent properly inwards, the moment he goes off true. A horse is said to be disunited to the right, when going to the right, and consequently leading with the right leg before, he leads with the left behind; and is said to be disunited to the left, when going to the left, and consequently leading with the left leg before, he leads with the right behind. A horse may at the same time be both false and disunited; in correcting both which faults, the same method must be used. He is both false and disunited to the right, when in going to the right he leads with the left leg before, and the right behind; notwithstanding that hinder leg be with propriety more forward under his belly than the left, because the horse is working to the right: And he is false and disunited to the left, when in going to the left he leads with the right leg before and the left behind; notwithstanding, as above, that hinder leg be with propriety more forward under his belly than the right, because the horse is working to the left.

In teaching men a right seat on horseback, the greatest attention must be given to prevent stiffness, and sticking by force in any manner upon any occa-

Of suppling
Horses

tion: stiffness disgraces every right work; and sticking serves only to throw a man (when displaced) a great distance from his horse by the spring he must go off with: whereas, by a proper equilibrating position of the body, and by the natural weight only of the thighs, he cannot but be firm and secure in his seat.

As the men become more firm, and the horses more supple, it is proper to make the circles less; but not too much so, for fear of throwing the horses forwards upon their shoulders.

Some horses, when first the bit is put into their mouths, if great care be not taken, will put their heads very low. With such horses, raise your right hand with the *bridoon* in it, and play at the same time with the bit in the left hand, giving and taking.

On circles, the rider must lean his body inwards; unless great attention be given to make him do it, he will be perpetually losing his seat outwards. It is scarce possible for him to be displaced, if he leans his body properly inwards.

SECT. III. *The Method of suppling Horses with Men upon them, by the EPAULE en dedans, &c. with and without a Longe, on Circles and on straight Lines.*

WHEN a horse is well prepared and settled in all his motions, and the rider firm, it will be proper then to proceed on towards a farther suppling and teaching of both.

In setting out upon this new work, begin by bringing the horse's head a little more inwards than before, pulling the inward rein gently to you by degrees. When this is done, try to gain a little on the shoulders, by keeping the inward rein the shorter, as before, and the outward one crossed over towards the inward one. The intention of these operations is this: The inward rein serves to bring in the head, and procures the bend; whilst the outward one, that is a little crossed, tends to make that bend perpendicular, and as it should be, that is to say, to reduce the nose and the forehead to be in a perpendicular line with each other: it also serves, if put forwards, as well as also crossed, to put the horse forwards, if found necessary; which is often requisite, many horses being apt in this and other works rather to lose their ground backwards than otherwise, when they should rather advance; if the nose were drawn in towards the breast beyond the perpendicular, it would confine the motion of the shoulders, and have other bad effects. All other bends, besides what are above specified, are false. The outward rein, being crossed, not in a forward sense, but rather a little backwards, serves also to prevent the outward shoulder from getting too forwards, and makes it approach the inward one; which facilitates the inward leg's crossing over the outward one, which is the motion that so admirably supples the shoulders. Care must be taken, that the inward leg pass over the outward one, without touching it: this inward leg's crossing over must be helped also by the inward rein, which you must cross towards and over the outward rein every time the outward leg comes to the ground, in order to lift and help the inward leg over it: at any other time, but just when the outward leg comes to the ground, it would be wrong to cross the inward

rein, or to attempt to lift up the inward leg by it; nay, it would be demanding an absolute impossibility, and lugging about the reins and horse to no purpose: because in this case, a very great part of the horse's weight resting then upon that leg, would render such an attempt not only fruitless, but also prejudicial to the sensibility of the mouth, and probably oblige him to defend himself; and, moreover, it would put the horse under a necessity of straddling before, and also of leading with the wrong leg, without being productive of any suppling motion whatsoever.

When the horse is thus far familiarly accustomed to what you have required of him, then proceed to effect by degrees the same crossing in his hinder legs. By bringing in the fore-legs more, you will of course engage the hinder ones in the same work: if they resist, the rider must bring both reins more inwards; and, if necessary, put back also, and approach his inward leg to the horse; and if the horse throws out his croup too far, the rider must bring both reins outwards, and, if absolutely necessary, he must also make use of his outward leg, in order to replace the horse properly: observing that the croup should always be considerably behind the shoulders, which in all actions must go first; and the moment that the horse obeys, the rider must put his hand and leg again in their usual position.

Nothing is more ungraceful in itself, more detrimental to a man's seat, or more destructive of the sensibility of a horse's sides, than a continual wriggling unsettledness in a horseman's legs, which prevents the horse from ever going a moment together true, steady, or determined.

A horse should never be turned, without first moving a step forwards: and when it is doing, the rider must not lift his elbow, and displace himself; a motion only of the hand from the one side to the other being sufficient for that purpose. It must also be a constant rule, never to suffer a horse to be stopped, mounted, or dismounted, but when he is well placed. The slower the motions are when a man or horse is taught any thing, the better.

At first, the figures worked upon must be great, and afterwards made less by degrees, according to the improvement which the man and horse make; and the cadenced pace also, which they work in, must be accordingly augmented. The changes from one side to the other, must be in a bold determined trot, and at first quite straight forwards, without demanding any side-motion on two *pistes*, which is very necessary to require afterwards when the horse is sufficiently suppled. By two *pistes* is meant, when the fore-parts and hinder parts do not follow, but describe two different lines.

In the beginning, a *longe* is useful on circles, and also on straight lines, to help both the rider and the horse; but afterwards, when they are grown more intelligent, they should go alone. At the end of the lesson, rein back; then put the horse, by a little at a time, forwards, by approaching both legs gently to his sides, and playing with the bridle: if he rears, push him out immediately into a full trot. Shaking the *caresson* on the horse's nose, and also putting one's self before him and rather near to him, will generally make him back, though he otherwise refuse to do it: and moreover a slight use and approaching of the rider's legs.

Directions
for Men
and Horses.

Of Head to the Wall, &c. legs, will sometimes be necessary in backing, in order to prevent the horse from doing it too much upon his shoulders; but the pressure of the legs ought to be very small, and taken quite away the moment that he puts himself enough upon his haunches. If the horse does not back upon a straight line properly, the rider must not be permitted to have recourse immediately to his leg, and so distort himself by it; but first try, if crossing over his hand and reins to which ever side may be necessary, will not be alone sufficient: which most frequently it will; if not, then employ the leg.

After a horse is well prepared and settled, and goes freely on in all his several paces, he ought to be in all his works kept, to a proper degree, upon his haunches, with his hinder legs well placed under him; whereby he will be always pleasant to himself and his rider, will be light in hand, and ready to execute whatever may be demanded of him, with facility, vigour, and quickness.

The common method that is used, of forcing a horse sidewise, is a most glaring absurdity, and very hurtful to the animal in its consequences; for instead of suppling him, it obliges him to stiffen and defend himself, and often makes a creature that is naturally benevolent, restive, frightened, and vicious.

For horses, who have very long and high fore-hands, and who poke out their noses, a running snaffle is of excellent use; but for such as bore and keep their heads low, a common one is preferable; though any horse's head indeed may be kept up also with a running one, by the rider's keeping his hands very high and forwards: but whenever either is used alone without a bridle upon horses that carry their heads low and that bore, it must be sawed about from one side to the other.

This lesson of the *epaule en dedans* should be taught to such people as are likely to become useful in helping to teach men and to break horses; and the more of such that can be found the better: none others should ever be suffered upon any occasion to let their horses look any way besides the way they are going. But all horses whatever, as likewise all men who are designed for the teaching others, must go thoroughly and perfectly through this excellent lesson, under the directions of intelligent instructors, and often practise it too afterwards; and when that is done, proceed to and be finished by the lessons of head and tail to the wall.

SECT. IV. Of the Head to the Wall, and of the Croup to the Wall.

THIS lesson should be practised immediately after that of the *epaule en dedans*, in order to place the horse properly the way he goes, &c. The difference between the head to the wall, and the croup to the wall, consists in this: in the former, the fore-parts are more remote from the centre, and go over more ground; in the latter, the hinder parts are more remote from the centre, and consequently go over more ground: in both, as likewise in all other lessons, the shoulders must go first. In riding-horses, the head to the wall is the easier lesson of the two at first, the line to be worked upon being marked by the wall, not far from his head.

Of Head to the Wall, &c. The motion of the legs to the right, is the same as that of the *epaule en dedans* to the left, and so *vice versa*; but the head is always bent and turned differently: in the *epaule en dedans*, the horse looks the contrary way to that which he goes; in this, he looks the way he is going.

In the beginning, very little bend must be required; too much at once would astonish the horse, and make him defend himself: it is to be augmented by degrees. If the horse absolutely refuses to obey, it is a sign that either he or his rider has not been sufficiently prepared by previous lessons. It may happen, that weakness or a hurt in some part of the body, or sometimes temper, though seldom, may be the cause of the horse's defending himself: it is the rider's business to find out from whence the obstacle arises; and if he finds it to be from the first mentioned cause, the previous lessons must be resumed again for some time; if from the second, proper remedies must be applied; and if from the last cause, when all fair means that can be tried have failed, proper corrections with coolness and judgment must be used.

In practising this lesson to the right, bend the horse to the right with the right rein; helping the left leg over the right (at the time when the right leg is just come to the ground), with the left rein crossed towards the right, and keeping the right shoulder back with the right rein towards your body, in order to facilitate the left leg's crossing over the right; and so likewise *vice versa* to the left, each rein helping the other by their properly mixed effects. In working to the right, the rider's left leg helps the hinder-parts on to the right, and his right leg stops them if they get too forwards; and so *vice versa* to the left: but neither ought to be used, till the hand being employed in a proper manner has failed, or finds that a greater force is necessary to bring about what is required than it can effect alone: for the legs should not only be corresponding with, but also subservient to, the hand; and all unnecessary aids, as well as all force, ought always to be avoided as much as possible.

In the execution of all lessons, the equilibrium of the rider's body is of great use to the horse: it ought always to go with and accompany every motion of the animal; when to the right, to the right; and when to the left, to the left.

Upon all horses, in every lesson and action, it must be observed, that there is no horse but has his own peculiar appui or degree of bearing, and also a sensibility of mouth, as likewise a rate of his own, which it is absolutely necessary for the rider to discover and make himself acquainted with. A bad rider always takes off at least the delicacy of both, if not absolutely destroys it. The horse will inform his rider when he has got his proper bearing in the mouth, by playing pleasantly and steadily with his bit, and by the spray about his chaps. A delicate and good hand will not only always preserve a light appui, or bearing, in its sensibility; but also of a heavy one, whether naturally so or acquired, make a light one. The lighter this appui can be made, the better; provided that the rider's hand corresponds with it; if it does not, the more the horse is properly prepared, so much the worse. Instances of this inconvenience of the best of appui,

To make
Horses
stand Fire,
&c.

appuis, when the rider is not equally taught with the horse, may be seen every day in some gentlemen, who try to get their horses *bitted* as they call it, without being suitably prepared themselves for riding them: the consequence of which is, that they ride in danger of breaking their necks; till at length, after much hauling about, and by the joint insensibility and ignorance of themselves and their grooms, the poor animals gradually become mere senseless unfeeling posts; and thereby grow, what they call, *settled*. When the proper appui is found, and made of course as light as possible, it must not be kept duly fixed without any variation, but be played with; otherwise one equally-continued tension of reins would render both the rider's hand and the horse's mouth very dull. The slightest and frequent giving and taking is therefore necessary to keep both perfect.

Whatever pace or degree of quickness you work in, be it ever so fast, or ever so slow, it must be cadenced; time is as necessary for an horseman as for a musician.

This lesson of the head and of the tail to the wall, must be taught every soldier: scarce any manœuvre can be well performed without it. In closing and opening of files, it is almost every moment wanted.

SECT. V. *The Method of making Horses stand Fire, Noises, Alarms, Sights, &c.*

IN order to make horses stand fire, the sound of drums, and all sorts of different noises, you must use them to it by degrees in the stable at feeding-time; and instead of being frightened at it, they will soon come to like it as a signal for eating.

With regard to such horses as are afraid of burning objects, begin by keeping them still at a certain distance from some lighted straw: caress the horse; and in proportion as his fright diminishes, approach gradually the burning straw very gently, and increase the size of it. By this means he will very quickly be brought to be so familiar with it, as to walk undaunted even through it.

As to horses that are apt to lie down in the water, if animating them, and attacking them vigorously, should fail of the desired effect, then break a straw-bottle full of water upon their heads, and let the water run into their ears, which is a thing they apprehend very much.

All troop-horses must be taught to stand quiet and still when they are shot off from, to stop the moment you present, and not to move after firing till they are required to do it; this lesson ought especially to be observed in light troops: in short, the horses must be taught to be so cool and undisturbed, as to suffer the rider to act upon him with the same freedom as if he was on foot. Patience, coolness, and temper, are the only means requisite for accomplishing this end. Begin by walking the horse gently, then stop and keep him from stirring for some time, so as to accustom him by degrees not to have the least idea of moving without orders: if he does, then back him; and when you stop him, and he is quite still, leave the reins quite loose.

To use a horse to fire-arms, first put a pistol or a carbine in the manger with his feed; then use him to the sound of the lock and the pan; after which,

when you are upon him, show the piece to him, presenting it forwards, sometimes on one side, sometimes on the other: when he is thus far reconciled, proceed to flash in the pan; after which, put a small charge into the piece, and so continue augmenting it by degrees to the quantity which is commonly used: if he seems uneasy, walk him forward a few steps slowly; and then stop, back, and caress him. Horses are often also disquieted and unsteady at the flash, and drawing, and returning of swords; all which they must be familiarized to by little and little, by frequency and gentleness.

It is very expedient for all cavalry in general, but particularly for light cavalry, that their horses should be very ready and expert in leaping over ditches, hedges, gates, &c. The leaps, of whatever sort they are, which the horses are brought to in the beginning, ought to be very small ones; the riders must keep their bodies back, raise their hands a little in order to help the fore-parts of the horse up, and be very attentive to their equilibrium. It is best to begin at a low bar covered with furze, which pricking the horse's legs, if he does not raise himself sufficiently, prevents his contracting a sluggish and dangerous habit of touching, as he goes over, which any thing yielding and not pricking would give him a custom of doing. Let the ditches you first bring horses to be narrow; and in this, as in every thing else, let the increase be made by degrees. Accustom them to come up to every thing which they are to leap over, and to stand coolly at it for some time; and then to raise themselves gently up in order to form to themselves an idea of the distance. When they leap well standing, then use them to walk gently up to the leap, and to go over it without first halting at it; and after that practice is familiar to them, repeat the like in a gentle trot, and so by degrees faster and faster, till at length it is as familiar to them to leap flying on a full gallop as any other way: all which is to be acquired with great facility by calm and soft means, without any hurry.

As horses are naturally apt to be frightened at the sight and smell of dead horses, it is advisable to habituate them to walk over and leap over carcases of dead horses: and as they are particularly terrified at this sight, the greater gentleness ought consequently to be used.

Horses should also be accustomed to swim, which often may be necessary upon service; and if the men and horses both are not used to it, both may be frequently liable to perish in the water. A very small portion of strength is sufficient to guide a horse, anywhere indeed, but particularly in the water, where they must be permitted to have their heads, and be no-ways constrained in any shape.

The unreasonable rage in Britain of cutting off all extremities from horses, is in all cases a very pernicious custom. It is particularly so in regard to a troop-horse's tail. It is almost incredible, how much they suffer at the picket for want of it: constantly fretting, and sweating, kicking about and laming one another, tormented, and stung off their meat, miserable, and helpless; whilst other horses, with their tails on, brush off all flies, are cool and at their ease, and mend daily; whilst the docked ones grow every hour more and more out of condition.

To make
Horses
stand Fire,
&c.

Of reining
back, &c.

SECT. VI. *The Method of reining back,—and of moving forwards immediately after:—of Piafing,—of Pillars, &c.*

NEVER finish your work by reining back with horses that have any disposition towards retaining themselves; but always move them forwards, and a little upon the haunches also, after it, before you dismount, (unless they retain themselves very much indeed, in which case nothing at all must be demanded from the haunches). This lesson of reining back, and piafing, is excellent to conclude with, and puts an horse well and properly on the haunches: It may be done, according as horses are more or less suppled, either going forwards, backing, or in the same place: if it is done well advancing, or at most on the same spot, it is full sufficient for a soldier's horse: For to piafe in backing, is rather too much to be expected in the hurry which cannot but attend such numbers both of men and horses as must be taught together in regiments. This lesson must never be attempted at all, till horses are very well suppled, and somewhat accustomed to be put together; otherwise it will have very bad consequences, and create restiveness. If they refuse to back, and stand motionless, the rider's legs must be approached with the greatest gentleness to the horse's sides; at the same time that the hand is acting on the reins to solicit the horse's backing. This seldom fails of procuring the desired effect, by raising one of the horse's fore-legs, which being in the air, has no weight upon it, and is consequently very easily brought backwards by a small degree of tension in the reins. When this lesson is well performed, it is very noble and useful, and has a pleasing air; it is an excellent one to begin teaching scholars with.

The lesson is particularly serviceable in the pillars, for placing scholars well at first. Very few regimental riding-houses have pillars, and it is fortunate they have not: for though, when properly made use of with skill, they are one of the greatest and best discoveries in horsemanship; they must be allowed to be very dangerous and pernicious, when they are not under the direction of a very knowing person.

SECT. VII. *The Method of curing Restivenesses, Vices, Defences, Starting, &c.*

WHENEVER a horse makes resistance, one ought, before remedy or correction is thought of, to examine very minutely all the tackle about him, if any thing hurts or tickles him, whether he has any natural or accidental weakness, or in short any the least impediment in any part. For want of this precaution, many fatal disasters happen: the poor dumb animal is frequently accused falsely of being restive and vicious; is used ill without reason; and, being forced into despair, is in a manner obliged to act accordingly, be his temper and inclination ever so well disposed. It is very seldom the case, that a horse is really and by nature vicious; but if such be found, he will despise all caresses, and then chastisements become necessary.

Correction, according as you use it, throws a horse into more or less violent action, which, if he be weak, he cannot support: but a vicious strong horse is to be considered in a very different light, being able both

to undergo and consequently to profit by all lessons; and is far preferable to the best-natured weak one upon earth. Patience and attention are never failing means to reclaim such a horse: in whatsoever manner he defends himself, bring him back frequently with gentleness (not however without having given him proper chastisement if necessary) to the lesson which he seems most averse to. Horses are by degrees made obedient, through the hope of recompense and the fear of punishment: how to mix these two motives judiciously together, is a very difficult matter; it requires much thought and practice; and not only a good head, but a good heart likewise. The coolest and best-natured rider will always succeed best. By a dexterous use of the incitements above-mentioned, you will gradually bring the horse to temper and obedience; mere force, and want of skill and coolness, would only tend to confirm him in bad tricks. If he be impatient or choleric, never strike him, unless he absolutely refuse to go forwards; which you must resolutely oblige him to do, and which will be of itself a correction, by preventing his having time to meditate and put in execution any defence by retaining himself. Resistance in horses, you must consider, is sometimes a mark of strength and vigour, and proceeds from spirit, as well as sometimes from vice and weakness. Weakness frequently drives horses into viciousness, when any thing wherein strength is necessary is demanded from them; nay, it inevitably must: great care therefore should always be taken to distinguish from which of these two causes any remedy or punishment is thought of. It may sometimes be a bad sign when horses do not at all defend themselves, and proceed from a sluggish disposition, a want of spirit, and of a proper sensibility. Whenever one is so fortunate as to meet with a horse of just the right spirit, activity, delicacy of feeling, with strength and good nature, he cannot be cherished too much; for such a one is a rare and inestimable jewel, and, if properly treated, will in a manner do every thing of himself. Horses are oftener spoiled by having too much done to them, and by attempts to dress them in too great an hurry, than by any other treatment.

If after a horse has been well suppled, and there are no impediments, either natural or accidental, if he still persists to defend himself, chastisements then become necessary: but whenever this is the case, they must not be frequent, but always firm, though always as little violent as possible; for they are both dangerous and very prejudicial when frequently or slightly played with, and still more so when used too violently.

It is impossible, in general, to be too circumspect in lessons of all kinds, in aids, chastisements, or caresses. Some have quicker parts, and more cunning, than others. Many will imperceptibly gain a little every day on the rider. Various, in short, are their dispositions and capacities. It is the rider's business to find out their different qualities, and to make them sensible how much he loves them, and desires to be loved by them; but at the same time that he does not fear them, and will be master.

Plunging is a very common defence among restive and vicious horses: if they do it in the same place, or backing, they must, by the rider's legs and spurs firmly

Of curing
Restiveness,
&c.

Plain Rules
for bad
Horsemen.

firmly applied, be obliged to go forwards, and their heads kept up high. But if they do it flying forwards, keep them back, and ride them gently and very slow for a good while together. Of all bad tempers and qualities in horses, those which are occasioned by harsh treatment and ignorant riders are the worst.

Rearing is a bad vice, and, in weak horses especially, a very dangerous one. Whilst the horse is up, the rider must yield his hand; and when the horse is descending, he must vigorously determine him forwards: if this be done at any other time but whilst the horse is coming down, it may add a spring to his rearing, and make him fall backwards. With a good hand on them, horses seldom persist in this vice; for they are themselves naturally much afraid of falling backwards. If this method fails, you must make the horse kick up behind, by getting somebody on foot to strike him behind with a whip; or, if that will not effect it, by pricking him with a goad.

Starting often proceeds from a defect in the sight; which therefore must be carefully looked into. Whatever the horse is afraid of, bring him up to it gently; if you caress him every step he advances, he will go quite up to it by degrees, and soon grow familiar with all sorts of objects. Nothing but great gentleness can correct this fault; for if you inflict punishment, the apprehension of chastisement becomes prevalent, and causes more starting than the fear of the object. If you let him go by the object, without bringing him up to it, you increase the fault, and confirm him in his fear: the consequence of which is, he takes his rider perhaps a quite contrary way from what he was going, becomes his master, and puts himself and the person upon him every moment in great danger.

With such horses as are to a very great degree fearful of any objects, make a quiet horse, by going before them, gradually entice them to approach nearer and nearer to the thing they are afraid of. If the horse, thus alarmed, be undisciplined and headstrong, he will probably run away with his rider; and if so, his head must be kept up high, and the snaffle sawed backwards and forwards from right to left, taking up and yielding the reins of it, as also the reins of the bit: but this latter must not be sawed backwards and forwards like the snaffle, but only taken up and yielded properly. No man ever yet did, or ever will, stop a horse, or gain any one point over him, by main force, or by pulling a dead weight against him.

SECT. VIII. Rules for bad Horsemen.

Thomson's
Rules.

In the first place, every horse should be accustomed to stand still when he is mounted. One would imagine this might be readily granted; yet we see how much the contrary is practised. When a gentleman mounts at a livery-stable, the groom takes the horse by the bit, which he bends tight round his under jaw: the horse striving to go on, is forced back; advancing again, he frets, as he is again stopped short, and hurt by the manner of holding him. The rider, in the mean time, mounting without the bridle, or at least holding it but slightly, is helped to it by the groom, who being thoroughly employed by the horse's flut-

Nº 157.

tering, has at the same time both bridle and stirrup to give. This confusion would be prevented, if every horse was taught to stand still when he is mounted. Forbid your groom, therefore, when he rides your horse to water, to throw himself over him from a horse-block, and kick him with his leg, even before he is fairly upon him. This wrong manner of mounting is what chiefly teaches your horse the vicious habit against which we are here warning. On the other hand, a constant practice of mounting in the proper manner, is all that is necessary to prevent a horse's going on till the rider is quite adjusted in the saddle.

The next thing necessary therefore is, that the rider should mount properly. The common method is to stand near the croup or hinder part of the horse, with the bridle held very long in the right hand. By this manner of holding the bridle before you mount, you are liable to be kicked; and when you are mounted, your horse may go on some time, or play what gambols he pleases, before the rein is short enough in your hand to prevent him. It is common likewise for an awkward rider, as soon as his foot is in the stirrup, to throw himself with all his force to gain his seat: which he cannot do, till he hath first overbalanced himself on one side or the other: he will then wriggle into it by degrees. The way to mount with ease and safety is, to stand rather before than behind the stirrup. In this posture take the bridle short, and the mane together in your left hand, helping yourself to the stirrup with your right, so that your toe may not touch the horse in mounting. When your left foot is in the stirrup, move on your right, till you face the side of the horse, looking across over the saddle. Then with your right hand grasp the hinder part of the saddle; and with that and your left, which holds the mane and bridle, lift yourself upright on your left foot. Remain thus a mere instant on your stirrup, only so as to divide the action into two motions. While you are in this posture, you have a sure hold with both hands, and are at liberty, either to get safely down, or to throw your leg over and gain your seat. By this deliberate motion, likewise, you avoid, what every good horseman would endeavour to avoid, putting your horse into a flutter.

When you dismount, hold the bridle and mane together in your left hand, as when you mounted; put your right hand on the pommel of the saddle, to raise yourself; throw your leg back over the horse, grasp the hinder part of the saddle with your right hand, remain a moment on your stirrup, and in every respect dismount as you mounted; only what was your first motion when you mounted, becomes the last in dismounting. Remember not to bend your right knee in dismounting, lest your spur should rub against the horse.

It may be next recommended to hold your bridle at a convenient length. Sit square, and let not the purchase of the bridle pull forward your shoulder; but keep your body even, as it would be if each hand held a rein. Hold your reins with the whole grasp of your hand, dividing them with your little finger. Let your hand be perpendicular; your thumb will then be uppermost, and placed on the bridle. Bend your wrist

Plain Rules
for bad
Horsemen.

Plain Rules
for bad
Horsemen.

wrist a little outward; and when you pull the bridle, raise your hand toward your breast, and the lower part of the palm rather more than the upper. Let the bridle be at such a length in your hand, as, if the horse should stumble, you may be able to raise his head, and support it by the strength of your arms, and the weight of your body thrown backward. If you hold the rein too long, you are subject to fall backward as your horse rises.

If, knowing your horse perfectly well, you think a tight rein unnecessary, advance your arm a little (but not your shoulder) towards the horse's head, and keep your usual length of rein. By this means, you have a check upon your horse, while you indulge him.

If you ride with a curb, make it a rule to hook on the chain yourself; the most quiet horse may bring his rider into danger, should the curb hurt him. If, in fixing the curb, you turn the chain to the right, the links will unfold themselves, and then oppose a farther turning. Put on the chain loose enough to hang down on the horse's under lip, so that it may not rise and press his jaw, till the reins of the bridle are moderately pulled.

If your horse has been used to stand still when he is mounted, there will be no occasion for a groom to hold him; but if he does, suffer him not to touch the reins, but that part of the bridle which comes down the cheek of the horse. He cannot then interfere with the management of the reins, which belongs to the rider only; and holding a horse by the curb (which is ever painful to him) is evidently improper when he is to stand still.

Another thing to be remembered is, not to ride with your arms and elbows as high as your shoulders; nor let them shake up and down with the motion of the horse. The posture is unbecoming, and the weight of the arms (and of the body too if the rider does not sit still) acts in continual jerks on the jaw of the horse, which must give him pain, and make him unquiet, if he has a tender mouth or any spirit.

Bad riders wonder why horses are gentle as soon as they are mounted by skilful ones, tho' their skill seems unemployed: the reason is, the horse goes at his ease, yet finds all his motions watched; which he has sagacity enough to discover. Such a rider hides his whip, if he finds his horse is afraid of it; and keeps his legs from his sides, if he finds he dreads the spur.

Avoid the ungraceful custom of letting your legs shake against the sides of the horse: and as you are not to keep your arms and elbows high, and in motion; so you are not to rivet them to your sides, but let them fall easy. One may, at a distance, distinguish a genteel horseman from an awkward one: the first sits still, and appears of a piece with his horse; the latter seems flying off at all points.

It is often said with emphasis, that such a one has no seat on horseback; and it means, not only that he does not ride well, but that he does not sit on the right part of the horse. To have a good seat, is to sit on that part of the horse, which, as he springs, is the centre of motion; and from which, of course, any weight would be with most difficulty shaken. As in the rising and falling of a board placed in *equilibrio*, the centre will be always most at rest; the true seat

will be found in that part of your saddle, into which your body would naturally slide, if you rode without stirrups; and is only to be preserved by a proper poise of the body, though the generality of riders imagine it is to be done by the grasp of the thighs and knees. The rider should consider himself as united to his horse in this point; and when shaken from it, endeavour to restore the balance.

Perhaps the mention of the two extremes of a bad seat may help to describe the true one. The one is, when the rider sits very far back on the saddle, so that his weight presses the loins of the horse; the other, when his body hangs forward over the pommel of the saddle. The first may be seen practised by grooms, when they ride with their stirrups affectedly short; the latter, by fearful horsemen on the least flutter of the horse. Every good rider has, even on the hunting saddle, as determined a place for his thighs, as can be determined for him by the bars of a demi-peak. Indeed there is no difference between the seat of either: only, as in the first you ride with shorter stirrups, your body will be consequently more behind your knees.

To have a good seat yourself, your saddle must sit well. To fix a precise rule might be difficult: it may be a *direction*, to have your saddle press as nearly as possible on that part which we have described as the point of union between the man and horse; however, so as not to obstruct the motion of the horse's shoulders. Place yourself in the middle or lowest part of it: sit erect; but with as little constraint as in your ordinary sitting. The ease of action marks the gentleman: you may repose yourself, but not lounge. The set and studied erectness acquired in the riding-house, by those whose deportment is not easy, appears ungentle and unnatural.

If your horse stops short, or endeavours by rising and kicking to unseat you, bend not your body forward, as many do in those circumstances: that motion throws the breech backward, and you off your fork or twist, and out of your seat; whereas, the advancing the lower part of your body, and bending back the upper part and shoulders, is the method both to keep your seat, and to recover it when lost. The bending your body back, and that in a great degree, is the greatest security in *flying leaps*; it is a security too, when your horse leaps *standing*. The horse's rising does not try the rider's seat; the lash of his hind legs is what ought chiefly to be guarded against, and is best done by the body's being greatly inclined back. Stiffen not your legs or thighs; and let your body be pliable in the loins, like the coachman's on his box. This loose manner of sitting will elude every rough motion of the horse; whereas the fixture of the knees, so commonly laid a stress on, will in great shocks conduce to the violence of the fall.

Was the cricket-player, when the ball is struck with the greatest velocity, to hold his hand firm and fixed when he receives it, the hand would be bruised, or perhaps the bones fractured by the resistance. To obviate this accident, he therefore gradually yields his hand to the motion of the ball for a certain distance; and thus by a due mixture of opposition and obedience, catches it without sustaining the least injury. The case is exactly the same in riding: the skilful horseman

Plain Rules
for bad
Horsemen.

will recover his poise by giving some way to the motion; and the ignorant horseman will be flung out of his seat by endeavouring to be fixed.

Stretch not out your legs before you; this will push you against the back of the saddle: neither gather up your knees, like a man riding on a pack; this throws your thighs upwards: each practice unseats you. Keep your legs straight down; and sit not on the most fleshy part of the thighs, but turn them inwards, so as to bring in your knees and toes: and it is more safe to ride with the ball of the foot pressing on the stirrup, than with the stirrup as far back as the heel; for the pressure of the heel being in that case behind the stirrup, keeps the thighs down.

When you find your thighs thrown upwards, widen your knees to get them and the upper part of your fork lower down on the horse. Grasp the saddle with the hollow or inner part of your thighs, but not more than just to assist the balance of your body: this will also enable you to keep your spurs from the horse's sides, and to bring your toes in, without that affected and useless manner of bringing them in practised by many. Sink your heels straight down; for while your heels and thighs keep down, you cannot fall: this (aided with the bend of the back) gives the security of a seat, to those who bear themselves up in their stirrups in a swift gallop, or in the alternate rising and falling in a full trot.

Let your seat determine the length of your stirrups, rather than the stirrups your seat. If more precision is requisite, let your stirrups (in the hunting saddle) be of such a length, as that, when you stand in them, there may be the breadth of four fingers between your seat and the saddle.

It would greatly assist a learner, if he would practise riding in a large circle, as directed sect. ii. without stirrups; keeping his face looking on the outward part of the circle so as not to have a full view of the horse's head, but just of that ear which is on the outward part of the circle; and his shoulder, which is towards the centre of the circle, very forward. By this means you learn to balance your body, and keep a true seat, independent of your stirrups: you may probably likewise escape a fall, should you at any time lose them by being accidentally shaken from your seat.

As the seat in some measure depends on the saddle, it may not be amiss to observe, that because a saddle with a high pommel is thought dangerous, the other extreme prevails, and the pommel is scarce allowed to be higher than the middle of the saddle. The saddle should lie as near the back-bone as can be, without hurting the horse; for the nearer you sit to his back, the better seat you have. If it does so, it is plain the pommel must rise enough to secure the withers from pressure: therefore, a horse whose withers are higher than common, requires a higher pommel. If, to avoid this, you make the saddle of a more straight line, the inconvenience spoken of follows; you sit too much above the horse's back, nor can the saddle form a proper seat. There should be no ridge from the button at the side of the pommel, to the back part of the saddle. That line also should be a little concave, for your thighs to lie at ease. In short, a saddle ought to be, as nearly as possible, as if cut out of the horse.

When you want your horse to move forward, raise his head a little, and touch him gently with your whip; or else, press the calves of your legs against his sides. If he does not move fast enough, press them with more force, and so till the spur just touches him. By this practice he will (if he has any spirit) move upon the least pressure of the leg. Never spur him by a kick; but if it be necessary to spur him briskly, keep your heels close to his sides, and slacken their force as he becomes obedient.

When your horse attempts to be vicious, take each rein separate, one in each hand, and advancing your arms forward, hold him very short. In this case, it is common for the rider to pull him hard, with his arms low. But the horse by this means having his head low too, has it more in his power to throw out his heels: whereas, if his head be raised very high, and his nose thrown out a little, which is consequent, he can neither rise before nor behind; because he can give himself neither of those motions, without having his head at liberty. A plank placed in *equilibrio*, cannot rise at one end unless it sinks at the other.

If your horse is headstrong, pull not with one continued pull, but stop, and back him often, just shaking the reins, and making little repeated pulls till he obeys. Horses are so accustomed to bear on the bit when they go forward, that they are discouraged if the rider will not let them do so.

If a horse is loose-necked, he will throw up his head at a continued pull; in which situation, the rider, seeing the front of his face, can have no power over him. When your horse does thus, drop your hand and give the bridle play, and he will of course drop his head again into its proper place: while it is coming down, make a second gentle pull, and you will find his mouth. With a little practice, this is done almost instantaneously; and this method will stop, in the distance of a few yards, a horse, which will run away with those who pull at him with all their might. Almost every one must have observed, that when a horse feels himself pulled with the bridle, even when he is going gently, he often mistakes what was designed to stop him, as a direction to bear on the bit and to go faster.

Keep your horse's head high, that he may raise his neck and crest; play a little with the rein, and move the bit in his mouth, that he may not press on it in one constant and continued manner: be not afraid of raising his head too high; he will naturally be too ready to bring it down, and tire your arms with its weight, on the least abatement of his mettle. When you feel him heavy, stop him, and make him go back a few paces: thus you break by degrees his propensity to press on his bridle.

You ought not to be pleased (though many are) with a round neck, and a head drawn in towards his breast: let your horse carry his head bridling in, provided he carries it high, and his neck arching upwards; but if his neck bends downwards, his figure is bad, his sight is too near his toes, he leans on the bridle, and you have no command over him. If he goes pressing but lightly on the bridle, he is the more sure-footed, and goes pleasanter; as your wrist only may guide him. If he hangs down his head, and makes you support the weight of that and his neck with your arms bearing

Horsemen

ing on his fore-legs, (which is called *being on his shoulders*), he will strike his toes against the ground, and stumble.

If your horse is heavy upon the bit, tie him every day, for an hour or two, with his tail to the manger, and his head as high as you can make him lift it, by a rein on each post of the stall, tied to each ring of the snaffle bit.

Horse-breakers and grooms have a great propensity to bring a horse's head *down*, and seem to have no feat without a strong hold by the bridle. They know indeed, that the head should yield to the reins, and the neck form an arch; but do not take the proper pains to make it an arch *upward*. A temporary effect of attempting to raise a horse's head, may perhaps be making him push out his nose. They will here tell you, that his head is too high already; whereas it is not the distance from his *nose*, but from the *top* of his head to the ground, which determines the head to be high or low. Besides, although the fault is said to be in the manner of carrying the head, it should rather be said to be in that of the neck; for if the neck was raised, the head would be more in the position of one set on a well formed neck.

The design therefore of lifting up the head, is to raise the neck, and *thereby* bring in the head; for even while the bridle makes the same line from the rider's hand to the bit, the horse's nose may be either drawn in, or thrust out, according as his neck is raised or depressed. Instead of what has been here recommended, we usually see colts broke with their heads caved down very low, their necks stiff, and not in the least suppled. When the breaking-tackle is left off, and they are mounted for the road, having more food and rest, they frequently plunge, and a second breaking becomes necessary. Then, as few gentlemen can manage their own horses, they are put into the hands of grooms, from whom they learn a variety of bad habits.

If, on the other hand, your horse carries his head (or rather his nose) too high, he generally makes some amends by moving his shoulders lightly, and going safely. Attend to the cause of this fault. Some horses have their necks set so low on their shoulders, that they bend first down, then upwards, like a stag's. Some have the upper line of their necks, from their ears to their withers, too short. A head of this sort cannot possibly bend inwards and form an arch, because the vertebræ (or neck bones) are too short to admit of flexure; for in long and short necked horses the number of the vertebræ is the same. In some, the jaw is so thick, that it meets the neck, and the head by this means has not room to bend. On the other hand, some have the under line from the jaw to the breast so short, that the neck cannot rise.

In all these cases you may gain a *little* by a nice hand with an easy bit; but no curb, martingale, or other forcible method, will *teach* a horse to carry his head or neck in a posture which nature has made *uneasy* to him. By trying to pull in his nose farther than he can bear, you will add a bad habit to nature. You could not indeed *contrive* a more effectual method to make him continually toss his nose up, and throw his foam over you.

The rule already given to ride a loose-necked horse,

will be a proper one for all light-mouthed horses: one caution being added, which is, always to search whether his saddle or girths may not in some way pinch him; and whether the bit may not hurt his lip by being too high in his mouth: because, whenever he frets from either of these causes, his head will not be steady.

It is a common custom to be always pulling at the bridle, as if to set off to advantage either the spirit of the horse, or the skill of the rider. Our horses therefore are taught to hold their heads low, and pull so, as to bear up the rider from the saddle, standing in his stirrups, even in the gentlest gallop: how very improper is this, we are experimentally convinced, when we happen to meet with a horse which gallops otherwise. We immediately say, *he canters excellently*, and find the ease and pleasure of his motion. When horses are designed for the race, and swiftness is the only thing considered, the method may be a good one.

It is not to be wondered that *dealers* are always pulling at their horses; that they have the spur constantly in their sides, and are at the same time continually checking the rein: by this means they make them bound, and champ the bit, while their rage has the appearance of spirit. These people ride with their arms spread, and very low on the shoulders of their horses: this method makes them stretch their necks, and gives a better appearance to their fore-hands; it conceals also a thick jaw, which, if the head was up, would prevent its yielding to the bit; it hides likewise the ewe-neck, which would otherwise show itself. Indeed, if you have a horse unsteady to the bit, formed with a natural heavy head, or one which carries his nose obstinately in the air, you must find his mouth where you can, and make the best of him.

Many horses are taught to start by whipping them for starting. How is it possible they can know it is designed as a punishment? In the riding-house, you teach your horse to rise up before, and to spring and lash out his hinder legs, by whipping him when tied between two pillars, with his head a little at liberty. If he understood this to be a punishment for doing so, he would not by that method learn to do it. He seems to be in the same manner *taught* to spring and fly when he is frightened. Most horses would go quietly past an object they were beginning to fly from, if their riders, instead of gathering up their bridles, and showing themselves so ready, should throw the reins loose upon their necks.

When a horse starts at any thing on one side, most riders turn him out of the road, to make him go up to what he starts at: if he does not get the better of his fear, or readily comply, he generally goes past the object, making with his hinder parts, or croup, a great circle out of the road; whereas, he should learn to keep straight on, without minding objects on either side.

If he starts at any thing on the left, hold his head high, and keep it straight in the road, pulling it *from* looking at the thing he starts at, and keeping your right leg hard pressed against his side, towards his flank: he will then go straight along the road. By this method, and by turning his head a little more, he may be forced with his croup close up to what frightened him; for as his head is pulled one way, his croup necessarily turns the other. Always avoid a

Plain Rules
for bad
Horsemen.

quarrel with your horse, if you can: if he is apt to start, you will find occasions enough to exercise his obedience, when what he starts at lies directly in his way, and you *must* make him pass; if he is not subject to start, you should not quarrel with him about a trifle.

It must be observed, however, that this rule in going past an object may perhaps be a little irregular in a managed horse, which will always obey the leg: but even such a horse, if he is really afraid, and not restive, it may not be amiss to make look another way; unless the object be something you would particularly accustom him to the sight of.

The case will also be different with a horse whose fear is owing to his being not used to objects; but such a one is not to be rode by any horseman to whom these rules are directed: the starting here meant arises merely from the horse's being pamper'd, and springing through liveliness.

The notion of the necessity of making a horse go immediately up to every thing he is afraid of, and not suffering him to become master of his rider, seems to be in general carried too far. It is an approved and good method to conquer a horse's fear of the sound of a drum, by beating one near to him at the time of feeding him: this not only familiarizes the noise to him, but makes it pleasant, as a fore-runner of his meat*; whereas, if he was whipped up to it, he might perhaps start at it as long as he lived. Might not this be applied to his starting at other things, and show that it would be better to suffer him (provided he does not turn back) to go a little from and avoid an object he has a dislike to, and to accustom him to it by degrees, convincing him, as it were, that it will not hurt him; than to punish him, quarrel with him, and perhaps submit to his will at last, while you insist on his overcoming his fear in an instant? If he sees a like object again, it is probable he will recollect his dread, and arm himself to be disobedient.

We are apt to suppose that a horse fears nothing so much as his rider: but may he not, in many circumstances, be afraid of instant destruction? of being crushed? of being drowned? of falling down a precipice? Is it a wonder that a horse should be afraid of a loaded waggon? may not the hanging load seem to threaten the falling on him? There cannot be a rule more general, than, in such a case, to show him there is room for him to pass. This is done by turning his head a very little from the carriage, and pressing your leg, which is farthest from it, against his side.

A horse is not to stop without a sign from his rider.—Is it not then probable, that when driven up to a carriage he starts at it, he conceives himself obliged either to attack or run against it? Can he understand the rider's spurring him with his face directed to it, as a sign for him to pass it? That a horse is easily alarmed for his face and eyes (he will even catch back his head from a hand going to caress him); that he will not go with any force, face to face, even to another horse (if in his power to stop); and that he sees perfectly sideways,—may be useful hints for the treatment of horses with regard to starting.

Though you ought not to whip a horse for starting, there can be no good effect from clapping his neck with your hand to encourage him. If one took any

notice of his starting, it should be rather with some tone of voice which he usually understood as an expression of dislike to what he is doing; for there is *opposition* mixed with his starting, and a horse will ever repeat what he finds has foiled his rider.

Notwithstanding the directions above given, of not pressing a horse up to a carriage he starts at; yet if one which you apprehend will frighten him meets you at a narrow part of the road, when you have once let him know he is to pass it, be sure you remain determined, and press him on. Do this more especially when part of the carriage has already passed you: for if, when he is frightened, he is accustomed to go back, and turn round, he will certainly do it if he finds, by your hand slackening, and legs not pressing, that you are irresolute; and this at the most dangerous point of time, when the wheels of the carriage take him as he turns. Remember not to touch the curb-rein at this time; it will certainly check him. It is not known to every one, that the person who would lead a horse by the bridle, should not turn his face to him when he refuses to follow him: if, besides this, he raises his arms, shows his whip, or pulls the bridle with jerks, he frightens the horse, instead of persuading him to follow; which a little patience may bring about.

Ride with a snaffle; and use your curb, if you have one, only occasionally. Choose your snaffle full and thick in the mouth, especially at the ends to which the reins are fastened. Most of them are made too small and long; they cut the horse's mouth, and bend back over the bars of his jaw, working like pincers.

The management of the curb is too nice a matter to enter on here, farther than to prescribe great caution in the use of it: a turn of the wrist, rather than the weight of your arm, should be applied to it. The elasticity of a rod, when it hath hooked a fish, may give you some idea of the proper play of a horse's head on his bridle; his spirit and his pliability are both marked by it.

A horse should never be put to do any thing in a curb which he is not ready at: you may force him, or pull his head any way with a snaffle; but a curb acts only in a straight line. It is true, that a horse will be turned out of one track into another by a curb, but it is because he knows it as a *signal*. When he is put to draw a chair, and does not understand the necessity he is then under of taking a larger sweep when he turns, you frequently see him *restive*, as it is then called: but put him on a snaffle, or buckle the rein to that part of the bit which does not curb him; and the horse submits to be pulled about, till he understands what is desired of him. These directions suppose your horse to have spirit, and a good mouth: if he has not, you must take him as he is, and ride him with such a bit as you find most easy to yourself.

When you ride a journey, be not so attentive to your horse's nice carriage of himself, as to your encouragement of him, and keeping him in good humour. Raise his head; but if he flags, you may indulge him with bearing a little more upon the bit than you would suffer in an airing. If a horse is lame, tender-footed, or tired, he naturally hangs upon his bridle.

Horsemen.

On a journey, therefore, his mouth will depend greatly on his strength and the goodness of his feet. Be then very careful about his feet, and let not a farrier spoil them. You will be enabled to keep them from danger, by the directions given under the article FARRIERY, p. 167.

Very few, although practised in riding, know they have any power over a horse but by the bridle; or any use for the spur, except to make him go forward. A little experience will teach them a farther use. If the left spur touches him (and he is at the same time prevented from going forward), he has a sign, which he will soon understand, to move sideways to the right. In the same manner to the left, if the right spur is closed to him: he afterwards, through fear of the spur, obeys a touch of the leg; in the same manner as a horse moves his croup from one side of the stall to the other, when any one strikes him with his hand. In short, his croup is guided by the leg, as his head is by the bridle. He will never disobey the leg, unless he becomes restive. By this means you will have a far greater power over him: he will move sideways, if you close one leg to him; and straight forward, if both: even when he stands still, your legs held near him will keep him on the watch; and with the slightest, unseen motion of the bridle upwards, he will raise his head, and show his forehead to advantage.

On this use of the legs of the rider, and guidance of the croup of the horse, are founded all the *airs* (as the riding-masters express themselves) which are taught in the manege; the passage, or side-motion of troopers to close or open their files, and indeed all their evolutions. But the convenience of some degree of this discipline for common use is the reason of mentioning it here. It is useful if a horse is apt to stumble or start. If to the first, by pressing your legs to his flank, and keeping up his head, he is made to go light on his fore-legs, which is aiding and supporting him; and the same if he does actually stumble, by helping him at the very instant to exert himself, while as yet any part of him remains not irrecoverably impressed with the precipitate motion. Hence this use of the hand and legs of the rider is called *giving aids* to a horse; for, as to holding up the weight of a heavy unactive horse, by mere pulling, it is as impossible as to recover him when falling down a precipice.

A horse is supported and helped by the hands and legs of his rider in every action they require of him; hence he is said to perform his *airs* by the *aids* from his rider.

The same manner is useful if a horse starts. For if when he is beginning to fly to one side, you leg on the side he is flying to, he stops his spring immediately. He goes past what he started at, keeping straight on, or as you choose to direct him; and he will not fly back from any thing if you press him with both legs. You keep his haunches under him, going down a hill; help him on the side of a bank; more easily avoid the wheel of a carriage; and approach more gracefully and nearer to the side of a coach or horseman. When a pampered horse curvets irregularly, and twists his body to and fro, turn his head either to the right or left, or both alternately (but without letting him move out of the track), and press your leg to the opposite side: your horse cannot then spring on his hind-legs to one side, because your leg prevents him; nor to the other, because his head looks that way, and a horse does not start and spring to the side on which he looks. Here it may not be amiss to observe the impropriety of the habit which many riders have, of letting their legs shake against the sides of the horse: if a horse is taught, they are then continually pressing him to violent action; and if he is not, they render him insensible and incapable of being taught. The fretting of a hot horse will hence be excessive, as it can no otherwise be moderated than by the utmost stillness of the seat, hands, and legs of the rider.

Colts at first are taught to *bear* a bit, and by degrees to *pull* at it. If they did not press it, they could not be guided by it. By degrees they find their necks stronger than the arms of a man; and that they are capable of making great opposition, and often of foiling their riders. Then is the time to make them supple and pliant in every part. The part which of all others requires most this pliancy is the neck. Hence the metaphor of *stiff-necked* for *disobedient*. A horse cannot move his head but with the muscles of his neck: this may be called his *helm*; it guides his course, changes and directs his motion.

The use of this pliancy in the different parts and limbs of a horse has been already shown in a former section. The present section being directed to the *unexperienced* horseman, it may suffice to add, that his idea of suppleness need only be, that of an ability and readiness in a horse to move every limb, on a sign given him by the hands or legs of his rider; as also, to bend his body, and move in a short compass, quick and collected within himself, so as instantly to be able to perform any other motion.

Horsemen.

H O R

Horsham.

HORSHAM, a town of Suffex, seated near St Leonard's forest, 38 miles from London. It has its name from Horfa, brother to Hengist the Saxon; and is one of the largest towns in the county. It has sent members to parliament ever since the 30th of Edward I. and is the place where the county gaol is held, and often the assizes. It is a borough by prescription, with the title of two bailiffs and burgrave-holders within and without the borough, &c. who elect the members of

H O R

Horstius.

parliament, and they are returned by the bailiffs chose yearly by a court-leet of the lord of the manor, who return four candidates to the steward, and he nominates two of them for the office. Here is a very fine church, and a well endowed free-school. Great store of poultry is bought up for London at its market on Saturday, and it has a patent also for a monthly market.

HORSTIUS (James), professor of medicine in the university.

Horstius university of Helmstadt, in the 16th century. He joined devotion with the knowledge and practice of physic. He carefully prayed to God to bless his prescriptions, and published a form of prayer upon this subject. He also wrote, 1. A treatise on the qualities of a good physician. 2. Another on the qualities of a good apothecary. 3. A treatise of the plague, in German. 4. A commentary *in libros Hippocratis de corde*, and other works.

HORSTIUS (Gregory), nephew of the former, called *the Æsculapius of Germany*, published several books, which are esteemed.

HORTAGILERS, in the grand signior's court, upholsterers, or tapestry-hangers. The grand signior has constantly 400 in his retinue when he is in the camp: these go always a day's journey before him, to fix upon a proper place for his tent, which they prepare first; and afterwards those of the officers, according to their rank.

HORTENSIUS (Quintus), a celebrated Roman orator, the cotemporary of Cicero, pleaded with universal applause at 19 years of age, and continued the same profession during 48 years. But being at last eclipsed by Cicero, he quitted the bar, and embraced a military life; became a military tribune, prætor, and afterwards consul, about 70 B. C. Cicero speaks of him in such a manner as makes us regret the loss of his orations. Hortensius had a wonderful memory, and delivered his orations without writing down a single word, or forgetting one particular that had been advanced by his adversaries. He died very rich, a little before the civil war, which he had endeavoured by all possible means to prevent.

HORTUS SICCUS, a DRY GARDEN; an appellation given to a collection of specimens of plants, carefully dried and preserved.

The value of such a collection is very evident, since 1000 minutæ may be preserved in the well dried specimens of plants, which the most accurate engraver would overlook. We shall therefore give two methods of drying and preserving a *hortus siccus*: the first by Sir Robert Southwell in *Philosophical Transactions*, n^o 237. ; and the other by Dr Hill, in his review of the works of the Royal Society, with his objections to Sir Robert's method.

According to the former gentleman, the plants are to be laid flat between papers, and then put between two smooth plates of iron, screwed together at the corners; and in this condition committed to a baker's oven for two hours. When taken out, they are to be rubbed over with a mixture of equal parts of aquafortis and brandy; and after this to be fastened down on paper with a solution of the quantity of a walnut of gum tragacanth dissolved in a pint of water. See **HERBAL**.

To this the Doctor objects, that the heat of an oven is much too uncertain to be employed in so nice an operation; and that the space of time ordered for continuing the plants in it is of no information, unless the degree of heat, and even the different nature of the plant as to its succulency and the firmness or tenderness of its fibres, be attended to; there being scarcely any two plants alike in these particulars: consequently the degree and duration of heat sufficient for one plant would destroy another. Beside which,

the acid used destroys the colour of many plants; and never recovers that of others lost in the drying; and frequently after the plant is fixed down, rots both the paper it is fixed to, and that which falls over it. Dr Hill's method is as follows. Take a specimen of a plant in flower, and with it one of its bottom leaves if it have any; bruise the stalk if too rigid, or slit it if too thick: spread out the leaves and flowers on paper, cover it with more paper, and lay a weight over all. At the end of 18 hours take out the plants, now perfectly flattened, and lay them on a bed of dry common sand; sift more dry sand over them to the depth of two inches, and thus let them lie about three weeks: the less succulent dry much sooner, but they take no harm afterward. If the floor of a garret be covered in spring with sand two inches deep, leaving space for walking to the several parts, it will receive the collection of a whole summer; the covering of sand being sifted over every parcel as laid in, they need no farther care from the time of laying them till they are taken up to be stuck on paper. The cement used by the Doctor is thus prepared: early in the spring, put two ounces of camphor into three quarts of water in a large bottle, shake it from time to time, and when the first collected plants are ready for the fastening down, put into a pint of the water, poured off into an earthen vessel that will bear the fire, two ounces of common glue, such as is used by the carpenters, and the same quantity of ichthyocolla beat to shreds; let them stand 36 hours, then gently boil the whole a few moments, and strain it off through a coarse cloth: this is to be warmed over a gentle heat when it is to be used, and the back of the plants smeared over with a painter's brush: after this lay them on paper, and gently press them for a few minutes, then expose them to the air a little; and finally, lay them under a small weight between quires of paper to be perfectly dried.

It is scarce to be conceived how strongly the water becomes impregnated with the camphor by this simple process: a part of it indeed flies off in the making of the cement and the using of it: but enough remains with the plants to prevent the breeding of insects in it. He farther observes, that plants may be dried very well without sand, by only putting them frequently into fresh quires of paper, or a few, by only pressing them between the leaves of a book: but the sand method preserves the colour best, and is done with least trouble.

Another method much better than that of the oven is the flattening and drying the plant by passing a common smoothing iron for linen over the papers between which it is laid: but for nice things the most perfect of all methods is that by a common sand heat, such as is used for chemical purposes. The cold sand is to be spread smooth upon this occasion, the plant laid on it carefully flattened, and a thick bed of sand sifted over: the fire is then to be made, and the whole process carefully watched until by a very gentle heat the plant be carefully dried. The colour of the tenderest herb may by this manner be preserved; and flowers, that can no way else be preserved, may be managed perfectly well thus.

HORUS, a renowned deity of ancient Egypt. He was an emblem of the sun. Plutarch (in his treatise *de Iside et Osiride*) says, "that virtue which presides over

Hortus,
Horus.

Horus. over the sun, whilst he is moving through space, the Egyptians called *Horus* and the Greeks *Apollo*." Job also calls *Ur* or *Orus* the sun—"If I gazed upon the sun (*Ur, Orus*) when he was shining, or on (*Fârêcha*) the moon walking in brightness, and my heart hath been severely enticed (*i. e.* to worship), or my mouth hath kissed my hand; this also were an iniquity to be punished by the judge, for I should have denied the God who is above." Chap. xxxi. ver. 26, 27, 28.

The interpretation left by Hermapion of the hieroglyphics engraved on the obelisk of Heliopolis (according to Ammianus Marcellinus), offers these remarkable words: "Horus is the supreme lord and author of time." These qualities, it is known, were chiefly attributed to Osiris: that they may apply, therefore, to Horus, he must necessarily denote the star of the day in certain circumstances; and this is what is explained to us by the oracle of Apollo of Claros:

Learn that the first of the gods is Jao.

He is called *invisible* in winter, Jupiter in the spring,

The *sun* in summer, and towards the end of autumn the tender *Jao*.

The star of the day, on attaining the summer solstice, and called *per excellentiam* The sun, is the same as Horus. In fact, the Egyptians represented him borne on lions, which signified his entrance into the sign of the lion. They who presided over the divine institutions, then placed sphynxes at the head of the canals and sacred fountains, to warn the people of the approaching inundation. Macrobius †, who informs us why the Greeks gave Horus the name of Apollo, confirms this sentiment: "In the mysteries (says he) they discover as a secret, which ought to be inviolable, that the sun arrived in the upper hemisphere, is called Apollo." These testimonies concur in proving, that this emblematical deity was no other than the star of day, passing through the signs of summer.

These lights may lead us to the explication of the sacred fable, which the priests published on the subject of Horus; for they enveloped in mystery every point of their religion. Plutarch gives it at length in his treatise of Isis and Osiris: Of the following are the principal traits. They said that he was the son of Osiris and of Isis; that Typhon, after killing his brother Osiris, took possession of the kingdom; that Horus, leaguering himself with Isis, avenged the death of his father, expelled the tyrant from his throne without depriving him of life, and reigned gloriously in Egypt. A person who has travelled ever so little in Egypt, easily discovers natural phenomena hid under the veil of fable. In the spring, the wind khamfin frequently makes great ravages there. It raises whirlwinds of burning sands, which suffocate travellers, darken the air, and cover the face of the sun in such a manner as to leave the earth in perfect obscurity. Here is the death of Osiris and the reign of Typhon. These hurricanes break loose usually in the months of February, March, and April. When the sun approaches the sign of the lion, he changes the state of the atmosphere, disperses these tempests, and restores the northerly winds, which drive before them the malignant vapours, and preserve in Egypt coolness and salubrity under a burning sky. This is the triumph of Horus over Typhon and his glorious reign. As the

natural philosophers acknowledge the influence of the moon over the state of the atmosphere, they united her with this god, to drive the usurper from the throne. The priests considering Osiris as the father of time, might bestow the name of his son on Horus, who reigned three months in the year. This, according to Mr Savary †, is the natural explication of this allegory. And all enlightened men, he thinks, must have understood this language, which was familiar to them. The people only, whose feeble sight extends no farther than the exterior, without diving into the true meaning of things, might regard these allegorical personages as real gods, and decree prayers and offerings to them.

Jablonski, who has interpreted the epithet of *Arueri*, which the Egyptians gave to Horus, pretends that it signifies *efficacious virtue*. These expressions perfectly characterise the phenomena which happened during the reign of this god. It is in summer, in fact, that the sun manifests all its power in Egypt. It is then that he swells the waters of the river with rains, exhaled by him in the air, and driven against the summits of the Abyssinian mountains; it is then that the husbandman reckons on the treasures of agriculture. It was natural for them to honour him with the name of *Arueri*, or *efficacious virtue*, to mark these auspicious effects.

HOSANNA, in the Hebrew ceremonies, a prayer which they rehearsed on the several days of the feast of tabernacles. It was thus called, because there was frequent repetition therein of the word *הושינא*, *serva nunc*, or *serva precor*; *i. e.* save us now; or, save us, we pray.

There are divers of these hosannahs. The Jews call them *hoshannoth*; *i. e.* the *hosannahs*. Some are rehearsed on the first day, others on the second, &c. which they call *hosanna* of the first day, *hosanna* of the second day, &c.

HOSANNA Rabba, or *Grand Hosanna*, is a name they give to their feast of tabernacles, which lasts eight days; because, during the course thereof, they are frequently calling for the assistance of God, the forgiveness of their sins, and his blessing on the new year; and to that purpose they make great use of the *hoshannoth*, or prayers above mentioned.—The Jews also apply the term *hosanna rabba*, in a more peculiar manner, to the seventh day of the feast of tabernacles; because they apply themselves more immediately on that day to invoke the divine blessing, &c.

HOSCHIUS (Sidronius), a jesuit, who was born at Marke, in the diocese of Ypres, in 1596, and died at Tongres in 1653. He wrote some elegies and other poems in Latin with great purity and elegance.

HOSE, from the Saxon *Hosa*, a stocking. See **STOCKING**.

HOSEA, a canonical book of the Old Testament, so called from the prophet of that name, its author, who was the son of Beri, and the first of the lesser prophets. He lived in the kingdom of Samaria, and delivered his prophecies under the reign of Jeroboam II. and his successors, kings of Israel; and under the reigns of Uzziah, Jotham, Ahaz, and Hezekiah, kings of Judah. His principal design is to publish the gross idolatries of the people of Israel and Judah, to denounce the divine vengeance against them, and to foretel the captivity in Assyria.

Hospinian,
Hospital.

HOSPINIAN (Rodolphus), one of the greatest writers that Switzerland has given birth to. He was born in 1547, at Altorf near Zurich; obtained the freedom of Zurich; and was made provisor of the abbey school. Notwithstanding this employment, he undertook a noble work of vast extent, which was a *History of the Errors of Popery*. Though he could not complete this work according to his plan, he published some considerable parts of it: what he published on the Eucharist, and another work called *Concordia Discors*, exceedingly exasperated the Lutherans. He did not reply to them; but turning his arms against the Jesuits, published *Historia Jesuitica*, &c. These writings gained him preferment; he being appointed archdeacon of Caroline church, and then minister of the abbey-church. He died in 1626; and there was an edition of his works published at Geneva 1681, in seven volumes in folio.

HOSPITAL, popularly **SPITAL**, a place or building erected, out of charity, for the reception and support of the poor, aged, infirm, sick, and otherwise helpless. The word is formed of the Latin *hospes*, "host, stranger." See **HOST**.

In the ages of the church, the bishop had the immediate charge of all the poor, both sound and diseased, as also of widows, orphans, strangers, &c.—When the churches came to have fixed revenues allotted them, it was decreed, that at least one fourth part thereof should go to the relief of the poor; and to provide for them the more commodiously, divers houses of charity were built, which are since denominated *hospitals*. They were governed wholly by the priests and deacons, under the inspection of the bishop. In course of time, separate revenues were assigned for the hospitals; and particular persons, out of motives of piety and charity, gave lands and money for erecting of hospitals. When the church discipline began to relax, the priests, who till then had been the administrators of hospitals, converted them into a sort of benefices, which they held at pleasure, without giving account thereof to any body; reserving the greatest part of the income to their own use; so that the intentions of the founders were frustrated.—To remove this abuse, the council of Vienne expressly prohibited the giving any hospital to secular priests in the way of a benefice; and directed the administration thereof to be given to sufficient and responsible laymen, who should take an oath, like that of tutors, for the faithful discharge thereof, and be accountable to the ordinaries.—This decree was executed and confirmed by the council of Trent.

In Britain, hospitals are buildings properly endowed, or otherwise supported by charitable contributions, for the reception and support of the poor, aged, infirm, sick, or helpless.

A charitable foundation laid thus for the sustenance and relief of the poor, is to continue for ever. Any person seized of an estate in fee, may, by deed inrolled in chancery, erect and found an hospital, and nominate such heads and governors therein as he shall think fit; and this charitable foundation shall be incorporated, and subject to the inspection and guidance of the heads and visitors nominated by the founder. Likewise such corporations shall have, take, and pur-

Nº 157.

chase lands, so as not to exceed 200l. a year, provided the same be not held of the king; and to make leases, reserving the accustomed yearly rent. See **CORPORATION**.

HOSPITAL (Michael de l'), chancellor of France in the 16th century, was one of the greatest men of his age, and had raised himself by degrees. He agreed to an edict much severer against the Protestants than he could have wished, to prevent the introduction of the inquisition. It was that of Romorantin. The speeches he made, in order to inspire a spirit of toleration, made him much suspected by the Roman Catholics, and extremely odious to the court of Rome. The maxims of state upon which he regulated himself were of great advantage to France, since he formed some disciples who opposed, in proper time, the pernicious attempts of the leaguers, and rendered them abortive.—His pacific views being disliked by Catharine de Medicis, who had contributed to his advancement, she excluded him from the council of war, and occasioned his disgrace. He retired, however, of his own accord, in 1568; and spent the rest of his life at his country-seat at Vignai, where he died in 1573, aged 68. His poems are esteemed. He also published some excellent speeches and memoirs.

HOSPITAL (William-Francis-Antony, marquis of), a great mathematician of France, was born of an ancient family in 1661. He was a geometrician almost from his infancy; for one day being at the duke of Rohan's, where some able mathematicians were speaking of a problem of Paschal's which appeared to them extremely difficult, he ventured to say, that he believed he could solve it. They were amazed at such presumption in a boy of 15, for he was then no more; nevertheless, in a few days he sent them the solution. He entered early into the army, and was a captain of horse; but being extremely short-sighted, and exposed on that account to perpetual inconveniences and errors, he at length quitted the army, and applied himself entirely to his favourite amusement. He contracted a friendship with Malbranche, and took his opinion upon all occasions. In 1693, he was received an honorary member of the academy of sciences at Paris; and he published a work upon Sir Isaac Newton's calculations, intitled, *L'Analyse des infinimens petits*. He was the first in France who wrote upon this subject; and on this account was regarded almost as a prodigy. He engaged afterwards in another work of the mathematical kind, in which he included *Les Sections Coniques, les Lieux Geometriques, la Construction des Equations, et Une Theorie des Courbes Mechaniques*: but a little before he had finished it, he was seized with a fever, of which he died Feb. 2. 1704, aged 43. It was published after his death.

HOSPITALITY, the practice of entertaining strangers. Dr Robertson, speaking of the middle ages, says, "Among people whose manners are simple, and who are seldom visited by strangers, hospitality is a virtue of the first rank. This duty of hospitality was so necessary in that state of society which took place during the middle ages, that it was not considered as one of those virtues which men may practise or not, according to the temper of their minds and the generosity of their hearts. Hospitality was enforced by statutes, and those who neglected the duty were liable

to

Hospita-
lity.

to punishment. The laws of the Slavi ordained that the moveables of an inhospitable person should be confiscated, and his house burnt. They were even so solicitous for the entertainment of strangers, that they permitted the landlord to steal for the support of his guest."

The hospitality of our British ancestors, particularly of the great and opulent barons, hath been much admired, and considered as a certain proof of the nobleness and generosity of their spirits. The fact is well attested. The castles of the powerful barons were capacious palaces, daily crowded with their numerous retainers, who were always welcome to their plentiful tables. They had their privy counsellors, their treasurers, marshals, constables, stewards, secretaries, chaplains, heralds, pursuivants, pages, henchmen or guards, trumpeters, minstrels, and in a word all the officers of a royal court. The etiquette of their families was an exact copy of that of the royal household; and some of them lived in a degree of pomp and splendor little inferior to that of the greatest kings. Richard Neville, earl of Warwick, we are told, "was ever had in great favour of the commons of the land, because of the exceeding household which he daily kept in all countries wherever he sojourned or lay: and when he came to London, he held such an house, that six oxen were eaten at a breakfast; and every tavern was full of his meat." The earls of Douglas in Scotland, before the fall of that great family, rivalled or rather exceeded their sovereigns in pomp and profuse hospitality. But to this manner of living, it is highly probable these great chieftains were prompted by a desire of increasing the number and attachment of their retainers, on which, in those turbulent times, their dignity, and even their safety, depended, as much as to the innate generosity of their tempers. Those retainers did not constantly reside in the families of their lords; but they wore their liveries and badges, frequently feasted in their halls, swelled their retinues on all great solemnities, attended them in their journeys, and followed them into the field of battle. Some powerful chieftains had so great a number of these retainers constantly at their command, that they set the laws at defiance, were formidable to their sovereigns, and terrible to their fellow-subjects; and several laws were made against giving and receiving liveries. But these laws produced little effect in this period.

Hospitality was not confined to the great and opulent, but was practised rather more than it is at present by persons in the middle and lower ranks of life. But this was owing to necessity, arising from the scarcity of inns, which obliged travellers and strangers to apply to private persons for lodging and entertainment; and those who received them hospitably acquired a right to a similar reception. This was evidently the case in Scotland in the first part of this period. James I. A. D. 1424, procured the following act of parliament. "It is ordanit, That in all burrow townis, and throuchfairis quhair commoun passages ar, that thair be ordanit hostillaries and resettis, havand stables and chalmers; and that men find with thame bread and aill, and all uther fude, alsweil for horse as men, for resonable price." But travellers had been so long accustomed to lodge in private houses, that these public inns were quite neglected; and those who kept

Vol. VIII. Part II.

them presented a petition to parliament, complaining, "That the liegis travelland in the realme, quhen they cum to burrowis and throuchfairis, herbreis thame not in hostillaries, bot with thair acquaintance and friendis." This produced an act prohibiting travellers to lodge in private houses where there were hostalries, under the penalty of 40 s. and subjecting those who lodged them to the same penalty.

The inhabitants of the Highlands and the Western Isles were remarkable for their hospitality and kindness to strangers, and still retain the same disposition. See HIGHLANDERS.

HOSPITALLERS, HOSPITALARI, an order of religious knights, who built an hospital at Jerusalem, wherein pilgrims were received. To these pope Clement V. transferred the effects and revenues of the Templars; whom, by a council held at Vienne, he suppressed for their many and great misdemeanours. These hospitallers were otherwise called *Knights of St John of Jerusalem*; and are the same with those whom we now call *Knights of Malta*.

HOSPITIUM, a term used in old writers either for an inn or a monastery, built for the reception of strangers and travellers. See INN and MONASTERY.

HOSPODAR, a title borne by the princes of Walachia and Moldavia, who receive the investiture of their principalities from the grand signior. He gives them a vest and standard; they are under his protection, and obliged to serve him, and he even sometimes deposes them; but in other respects they are absolute sovereigns within their own dominions.

HOST, HOSPE, a term of mutual relation, applied both to a person who lodges and entertains another, and to the person thus lodged, &c.—The word is formed of the Latin *hospes*, which some will have thus called, *quasi hospitium* or *ostium petens*; for *ostium* was anciently written with an aspirate.—Thus the inn-keeper says, he has a good *host*, in speaking of the traveller who lodges with him: and the traveller, again, says, he has a kind *host*, in speaking of his landlord.

It must be observed then, that it was the custom among the ancients, when any stranger asked for lodging, for the master of the house, and the stranger, each of them to set a foot on their own side of the threshold, and swear they would neither of them do any harm to the other. It was this ceremony that raised so much horror against those who violated the law or right of hospitality on either side; inasmuch as they were looked on as perjured.

Instead of *hospes*, the ancient Latins called it *hospis*; as Cicero himself informs us: though, in course of time, *hospis* came to signify an enemy; so much was the notion of hospitality altered.

Host is also used by way of abbreviation for *hostia*, a victim or sacrifice offered to the Deity. In this sense, *host* is more immediately understood of the person of the Word incarnate, who was offered up an *host* or *hostia* to the Father on the cross for the sins of mankind. See HOSTIA.

Host, in the church of Rome, a name given to the elements used in the eucharist, or rather to the consecrated wafer; which they pretend to offer up every day a new *host* or sacrifice for the sins of mankind.—They pay adoration to the *host*, upon a false

presumption that the elements are no longer bread and wine, but transubstantiated into the real body and blood of Christ. See TRANSUBSTANTIATION.—Pope Gregory IX. first decreed a bell to be rung, as the signal for the people to betake themselves to the adoration of the host.—The vessel wherein the hosts are kept is called the *cibory*; being a large kind of covered chalice.

HOSTAGE, a person given up to an enemy as a security for the performance of the articles of a treaty.

HOSTIA, Host, in antiquity, a victim offered in sacrifice to a deity.

The word is formed from *hostis*, “enemy;” it being the custom to offer up a sacrifice before they joined battle, to render the gods propitious; or, after the battle was over, to give them thanks. Some choose to derive the word from *hostio*, q. d. *ferio*, “I strike.” Isidore on this word remarks, that the name *hostia* was given to those sacrifices which they offered before they marched to attack an enemy, (*antequam ad hostem pergerent*); in contradistinction from *victimæ*, which were properly those offered after the victory.

Hostia also signified the lesser sorts of sacrifice, and *victimæ* the larger. A. Gellius says, that every priest, indifferently, might sacrifice the *hostia*, but that the *victimæ* could be offered by none but the conqueror himself. But, after all, we find these two words promiscuously used one for the other by ancient writers. We read of many kinds of *hostiæ*: as *hostiæ puræ*, which were pigs or lambs ten days old; *hostiæ præcidanæ*, sacrifices offered the day before a solemn feast; *hostiæ bidentes*, sacrifices of sheep or other animals of two years old; *hostiæ eximie*, a sacrifice of the flower of the flock; *hostiæ succedanæ*, sacrifices offered after others which had exhibited some ill omen; *hostiæ ambarvales*, victims sacrificed after having been solemnly led round the fields at the *ambarvalia*; *hostiæ amburbiales*, victims slain after the *amburbium*; *hostiæ canearæ* or *caviaræ*, victims sacrificed every fifth year by the college of pontiffs, in which they offered the part of the tail called *caviar*; *hostiæ prodigiæ*, sacrifices in which the fire consumed all, and left nothing for the priests; *hostiæ piaculares*, expiatory sacrifices; *hostiæ ambegnæ* or *ambiegnæ*, sacrifices of cows or sheep that had brought forth twins; *hostiæ larugæ*, victims offered to predict future events from; *hostiæ mediales*, black victims offered at noon.

HOSTILITY, the action of an enemy, or a state of warfare. The word is Latin, *hostilitas*, formed of the primitive *hostis*, which signifies “enemy;” and which anciently signified “stranger,” *hospes*.

HOT-BEDS, in gardening, beds made with fresh horse-dung, or tanner’s bark, and covered with glassess to defend them from cold winds.

By the skilful management of hot-beds, we may imitate the temperature of warmer climates; by which means, the seeds of plants brought from any of the countries within the torrid zone may be made to flourish even under the poles.

The hot-beds commonly used in kitchen-gardens, are made with new horse dung mixed with the litter of a stable, and a few sea-coal-ashes, which last are of service in continuing the heat of the dung. This should remain six or seven days in a heap; and being then turned over, and the parts mixed well together, it should be again cast into a heap; where it may continue five or six days longer, by which time it will

have acquired a due heat. These hot-beds are made in the following manner: In some sheltered part of the garden, dig out a trench of a length and width proportionable to the frames you intend it for; and if the ground be dry, about a foot or a foot and a half deep; but if it be wet, not above six inches: then wheel the dung into the opening, observing to stir every part of it with a fork, and to lay it exactly even and smooth on every part of the bed, laying the bottom part of the heap, which is commonly free from litter, upon the surface of the bed: and if it be designed for a bed to plant out cucumbers to remain for good, you must make a hole in the middle of the place designed for each light about ten inches over, and six deep, which should be filled with good fresh earth, thrusting in a stick to show the places where the holes are; then cover the bed all over with the earth that was taken out of the trench, about four inches thick, and put on the frame, letting it remain till the earth be warm, which commonly happens in three or four days after the bed is made, and then the plants may be placed in it. But if your hot-bed be designed for other plants, there need be no holes made in the dung; but after having smoothed the surface with a spade, you should cover the dung about three or four inches thick with good earth, putting on the frames and glassess as before. In making these beds, care must be taken to settle the dung close with a fork; and if it be pretty full of long litter, it should be trod down equally on every part. During the first week or ten days after the bed is made, you should cover the glassess but slightly in the night, and in the day-time carefully raise them, to let out the steam: but as the heat abates, the covering should be increased; and as the bed grows cold, new hot dung should be added round the sides of it.

The hot-bed made with tanner’s bark is, however, much preferable to that described above, especially for all tender exotic plants and fruits, which require an even degree of warmth to be continued for several months, which cannot be effected with horse-dung. The manner of making them is as follows: Dig a trench about three feet deep, if the ground be dry; but if wet, it must not be above a foot deep at most, and must be raised two feet above the ground. The length must be proportioned to the frames intended to cover it; but it should never be less than ten or twelve feet, and the width not less than six. The trench should be bricked up round the sides to the above-mentioned height of three feet, and filled in the spring with fresh tanner’s bark that has been lately drawn out of their vats, and has lain in a round heap, for the moisture to drain out of it, only three or four days: as it is put in, gently beat it down equally with a dung-fork; but it must not be trodden, which would prevent its heating, by settling it too close: then put on the frame, covering it with glassess; and in about ten days or a fortnight it will begin to heat; at which time plunge your pots of plants or seed into it, observing not to tread down the bark in doing it. These beds will continue three or four months in a good temper of heat; and if you stir up the bark pretty deep, and mix a load or two of fresh bark with the old when you find the warmth decline, you will preserve its heat two or three months longer. Many lay

Hot.

Hotel
||
Hottentots

lay some hot horse-dung in the bottom of the trench under the bark; but this ought never to be practised unless the bed is wanted sooner than the bark would heat of itself, and even then there ought only to be a small quantity of dung at the bottom.

The frames which cover these beds, should be proportioned to the several plants they are designed to contain. If they are to cover the ananas or pineapple, the back part should be three feet high, and the lower part 15 inches: if the bed be intended for taller plants, the frame must be made of a depth proportionable to them: but if it be for sowing of seeds, the frame need not be above 14 inches high at the back, and 7 in the front; by which means the heat will be much greater.

Hot-House. See STOVE and HYPOCAUSTUM.

HOTEL, a French term, anciently signifying a house or dwelling place.—It is now more commonly used for the palaces or houses of the king, princes, and great lords. In this sense they say, the *hotel de Conde*, *hotel de Conti*, *hotel du Louvre*, &c.

The grand *prevot de l'hotel*, is the first judge of the officers of the king's household. His jurisdiction is much like that of lord steward of the household of the king of England.

The *hotel de ville* is what we call a *town-house* or *town hall*.

HOTEL, is likewise used for a large inn, also for a large lodging-house ready furnished.

HOTMAN (Francis), one of the most learned civilians in the 16th century. He professed law at Bourges: but, on account of religion, retired to Geneva, read lectures on civil law there, and published books with such strength against the persecutors, that great promises were made to him to engage him not to write any more in that manner; but he did not regard their offers. He died at Basil in 1590. His *Franco-Gallia* is well known, having been done in English by lord Moleworth. Some persons think he was the author of *Vindicia contra Tyrannos*. All his works were printed at Geneva in 1590, in 3 vols folio.

HOTTENTOTS, a people in the southern part of Africa, whose country surrounds the empire of Monomotapa, in form of a horse-shoe, extending, according to Magin, from the Negroest of Cabo as far as the Cape of Good Hope; and from thence northward to the river Magnica, or Rio de St Spirita, including Mattatan a distinct kingdom. According to Sanutus, this coast, beginning at the Mountains of the Moon under the tropic of Capricorn in $23^{\circ}\frac{1}{4}$ S. Lat. extends north beyond the Cape to the coast of Zanguebar; having the Indian sea on the east, the Ethiopic on the west, the southern ocean on the south; and on the north the kingdoms of Mattatan, Monomotapa, and the coast of Zanguebar, or rather the Mountains of the Moon, which divide it from the rest of the continent.

The Europeans first became acquainted with this country in the year 1493, when Bartholomew Diaz, a Portuguese admiral, discovered the most southerly point of Africa now called the *Cape of Good Hope*, but by him *Cabo dos todos tormentos*, or Cape of all Plagues, on account of the storms he met with in the neighbourhood; but John, then king of Portugal, ha-

ving from the account of Diaz concluded that a passage to the East Indies was now discovered, changed the name to that of the *Cape of Good Hope*, which it still retains. In 1497, it was circumnavigated by Gasco de Gama, who made a voyage to India that way; however, it remained useless to Europeans till the year 1650, when Van Riebeck a Dutch surgeon first saw the advantages that would accrue to the East India company in Holland from a settlement at such a convenient distance both from home and from India. The colony which he planted has ever since continued in the hands of the Dutch, has greatly increased in value, and is visited by all the European ships trading to the East Indies. See *Good-Hope*.

The country now possessed by the Dutch is of pretty considerable extent, and comprehends that part of the African coast on the west called *Terra de Natal*. It is naturally barren and mountainous; but the industry of the Dutch hath overcome all natural difficulties, and it now produces not only a sufficiency of all the necessaries of life for the inhabitants, but also for the refreshment of all the Europeans who pass and repass that way.

The coast abounds in capes, bays, and roads. Thirty leagues to the east of the Cape of Good Hope, in S. Lat. $34^{\circ} 21'$ is another Cape which runs out beyond 35° , called by the Portuguese, who first doubled it, *Cabo dos Agulhas*, or the *Cape of Needles*, on account of some strange variations in the magnetical needle observed as they came near it. Near this Cape is a flat shore, with plenty of fish: it begins in the west near a fresh-water river, and, extending 15 leagues in the main sea, ends in the east near *Fish-bay*. Cabo Falso, so called by the Portuguese, who returning from India mistook it for the Cape of Good Hope, lies to the eastward between these two capes, about eight or nine leagues beyond that of Good Hope. Along the coasts, on both sides of the Cape of Good Hope, are many fine bays. Twenty-seven leagues to the north-west is Saldonha bay, so named from a Portuguese captain shipwrecked on the coast. The largest and most commodious is *Table Bay*, on the south, and near the mountain of that name, six leagues in circumference, with four-fathom water close to the beach. Opposite to this bay is *Robu Eilan*, or the island of Rabbits, in $34^{\circ} 30'$ S. Lat. 67 leagues east from the Cape of Good Hope. Peter Both, in 1661, discovered a bay, which he named *Uleest*, sheltered only from north winds, in which is a small island, and on the west a rivulet of fresh water extremely convenient for European mariners. Twenty-five or thirty leagues farther east, Both discovered *Marshal Bay*, afterwards named by the Portuguese *Seno Formoso*. Next to this is *Seno de Lago*, from its resemblance to a lake. There are several roads in this bay, and an island called *Ilha dos Caos*. Cabo de S. Francisco, and Cabo das Serras are marked upon charts between these two bays. Near the latter of these capes is Cabo de Arecito, and the island Contento; and something more north-east is St Christopher's river, called *San Christovano* by the Portuguese, and by the Hottentots *Nagod*. The country beyond this river was called by the Portuguese, who discovered it on the day of our Lord's nativity, *Terra de Natal*. Between the Cape of Good Hope and Cabo das Agulhas are the Sweet,

Hottentots.

Hottentots. Salt, and Jagulina rivers, which run into the sea, and Sweet-water river flows from the Table-mountain.

The most remarkable mountains in this country are, Table-mountain, Devil's Tower, Lion's Head, and the Tiger-hills. The three first lie near Table-bay, and surround Table-valley, where the Cape town stands. (See the article *Good-Hope*.) Mr Forster, in his voyage, informs us, that "the extremity of Africa towards the south is a mass of high mountains, of which the outermost are craggy, black, and barren, consisting of a coarse granite, which contains no heterogeneous parts, such as petrified shells, &c. nor any volcanic productions. The ground gradually rises on all sides towards the three mountains which lie round the bottom of the bay, keeping low and level only near the sea-side, and growing somewhat marshy in the Isthmus between False and Table Bays, where a salt rivulet falls into the latter. The marshy part has some verdure, but intermixed with a great deal of sand. The higher grounds, which, from the sea-side, have a parched and dreary appearance, are, however, covered with an immense variety of plants, among which are a prodigious number of shrubs, but scarce one or two species that deserve the name of *trees*. There are also a few small plantations wherever a little run of water moistens the ground. The ascent of Table-mountain is very steep and difficult, on account of the number of loose stones which roll away under the feet of the traveller. About the middle of the mountain is a bold, grand chasm, whose walls are perpendicular, and often impending rocks piled up in strata. Small rills of water ooze out of crevices, or fall from precipices in drops, giving life to hundreds of plants and low shrubs in the chasm. The summit of the mountain is nearly level, very barren, and bare of soil; several cavities, however, are filled with rain water, or contain a small quantity of vegetable earth, from whence a few odoriferous plants draw their nourishment. Some antelopes, howling baboons, solitary vultures, and toads, are sometimes to be met with on the mountain. The view from thence is very extensive and picturesque. The bay seems a small pond or basin, and the ships in it dwindled to little boats; the town under our feet, and the regular compartments of its gardens, look like the work of children."

Most accounts of this country that have been published mention a surprising phenomenon which is annually to be seen on the top of Table-hill from September to March; namely, a white cloud hovering on its top, and called by sailors *the Devil's table-cloth*. (See the article *Good-Hope*.) This cloud is said by some to appear at first no bigger than a barley-corn; then increases to the size of a walnut, and soon after covers the whole top of the mount. But, according to Mr Kolben, it is never less, even on its first appearance, than the size of a large ox, often bigger. It hangs in several fleeces over the Table-hill and the Wind or Devil's hill; which fleeces, at last uniting, form a large cloud that covers the summits of these two hills. After this has rested for some time without change or motion, the wind bursts out suddenly from it with the utmost fury. The skirts of the cloud are white, but seem much more compact than the matter of common clouds; the upper parts are of a leaden colour. No rain falls from it, but sometimes it dis-

covers a great deal of humidity; at which times it is of a darker colour, and the wind issuing from it is broken, raging by fits of short continuance. In its usual state, the wind keeps up its first fury unabated for one, two, three, or eight days; and sometimes for a whole month together. The cloud seems all the while undiminished, though little fleeces are from time to time detached from it, and hurried down the sides of the hills, vanishing when they reach the bottom, so that during the storm the cloud seems to be supplied with new matter. When the cloud begins to brighten up, these supplies fail, and the wind proportionably abates. At length, the cloud growing transparent, the wind ceases. During the continuance of these south-east winds, the Table-valley is torn by furious whirlwinds. If they blow warm, they are generally of short duration; and in this case the cloud soon disappears. This wind rarely blows till after sunset, and never longer than till towards midnight, though the cloud remains; but then it is thin and clear: but when the wind blows cold, it is a sure sign that it will last for some time, an hour at noon and midnight excepted; when it seems to lie still to recover itself, and then lets loose its fury anew.

The Europeans at the Cape consider the year as divided into two seasons, which they term *monsoons*. The wet monsoon or winter, and the dry one or summer. The first begins with our spring in March; the latter with September, when our summer ends. In the summer monsoon reign the south-east winds already mentioned; which, though they clear and render the air more healthy, yet make it difficult for ships outward bound to enter Table-bay. In the bad season, the Cape is much subject to fogs; and the north-west winds and rain make the inhabitants stay much at home. But there are frequent intermissions and many clear days till June and July; when it rains almost continually, and from thence till summer. The weather in winter is cold, raw, and unpleasant; but never more rigorous than autumn in Germany. Water never freezes to above the thickness of half a crown; and as soon as the sun appears, the ice is dissolved. The Cape is rarely visited by thunder and lightning, excepting a little near the turn of the seasons, which never does any hurt. During the continuance of the south-east winds which rage in summer, the sky is free of all clouds except that on the Table and Wind Hills already mentioned; but during the north-west winds, the air is thick, and loaded with heavy clouds big with rain. If the south-east winds should cease for any length of time, the air becomes sickly by reason of the sea-weeds driving ashore and rotting; hence the Europeans are at such times affected with head-achs and other disorders: but, on the other hand, the violence of those winds subjects them to inflammations of their eyes, &c.

The natives of this country are called *Hottentots*, in their own language; a word of which it is vain to inquire the meaning, since the language of this country can scarce be learned by any other nation. The *Hottentot* language is indeed said to be a composition of the most strange and disagreeable sounds, deemed by many the disgrace of speech, without human sound or articulation, resembling rather the noise of irritated turkies, the chattering of magpies, hooting of owls, and

depending

Hottentots. depending on extraordinary vibrations, inflexions, and clappings of the tongue against the palate.—If this account is true, however, it is obvious, that all the relations we have concerning the religion, &c. of the Hottentots derived from themselves, must fall to the ground, as nobody can pretend to understand a language in itself unintelligible. The manners and customs of those people, however, are easily observable, whether they themselves give the relation or not; and if their language is conformable to them, it is no doubt of a nature sufficiently wonderful.

Many accounts have been published concerning the extreme nastiness and filthy customs of the Hottentots; but from the observations of late travellers it appears, that these have either been exaggerated, or that the Hottentots (which is not improbable) have in some measure laid aside their former manners. Dr Sparrman describes them in much less disgusting terms, and M. Vaillant seems to have been charmed with their innocence and simplicity. According to the Doctor, these people are as tall as the generality of Europeans, though more slender in their persons, which he attributes to their scanty supply of food, and not accustoming themselves to hard labour. The characteristic of the nation, however, and which he thinks has not been observed by any one before, is, that they have small hands and feet in proportion to the other parts of their body. The distance between the eyes appears greater than in Europeans, by reason of the root of the nose being very low. The tip is pretty flat, and the iris of the eye has generally a dark-brown cast, sometimes approaching to black. Their skin is of a yellowish brown, something like that of an European who has the jaundice in a high degree; though this colour does not in the least appear in the whites of the eyes. Their lips are thinner than those of their neighbours the *Negroes*, *Caffres*, or *Mozambiques*. “In fine (says our author) their mouths are of a middling size, and almost always furnished with a set of the finest teeth that can be seen; and, taken together with the rest of their features, as well as their carriage, shape, and every motion, in short their *tout ensemble* indicates health and delight, or at least an air of *sans souci*. This careless mien, however, discovers marks at the same time both of alacrity and resolution; qualities which the Hottentots, in fact, can show upon occasion.” The hair of the head is black and frizzled, though not very close; and has so much the appearance of wool, that it would be taken for it, were it not for its harshness. They have but seldom any appearance of a beard, or hair upon other parts of their bodies; and when any thing of this kind happens to be visible, it is always very slight.

A general opinion has prevailed, that the Hottentot women have a kind of natural veil which covers the sexual parts; but this is denied by our author. “The women (says he) have no parts uncommon to the rest of their sex: but the clitoris and nymphæ, particularly of those who are past their youth, are pretty much elongated; a peculiarity which has undoubtedly got footing in this nation in consequence of the relaxation necessarily produced by the method they have of besmearing their bodies, their slothfulness, and the warmth of the climate.”

The Hottentots besmear all their bodies copiously

with fat mixed up with a little foot. “This (says our author) is never wiped off; on the contrary, I never saw them use any thing to clean their skins, excepting that when in greasing the wheels of their waggon, their hands were besmeared with tar and pitch, they used to get it off very easily with cow-dung, at the same time rubbing their arms into the bargain up to the shoulders with this cosmetic; so that as the dust and other filth, together with their footy ointment, and the sweat of their bodies, must necessarily, notwithstanding it is continually wearing off, in some measure adhere to the skin, it contributes not a little to conceal the natural hue of the latter, and at the same time to change it from a bright umber-brown to a brownish-yellow colour, obscured with filth and nastiness.”—The Doctor was enabled to discover the natural colour of the Hottentots by means of the nicety of some Dutch farmers wives, who had made their Hottentot girls wash and scour their skins, that they might be less filthy in looking after the children, or doing any other work that required cleanliness. Many of the colonists, however, are of opinion, that this operation of washing is no improvement to the look of an Hottentot; but that their natural yellow is fully as disagreeable as the black or brown colour of the ointment; and that the washed skin of a native of this country seems to be deficient in dress, like shoes that want blacking. This the Doctor does not pretend to determine; though, whatever may be supposed deficient in look we should think, must be made up in cleanliness.

The Hottentots perfume their bodies, by daubing them all over with the powder of an herb, the smell of which is at once rank and aromatic, approaching to that of the poppy mixed with spices. For this purpose they use various species of the *diosma*, called by them *bucku*, and which they imagine to be very efficacious in the cure of disorders. One species of this plant, growing about *Goud's-rivier*, is said to be so valuable, that no more than a thimble-full of its powder is given in exchange for a lamb.

By the ointment of foot and grease stuck full of the powder of *bucku*, a paste is formed which defends the bodies of the Hottentots in a great measure from the action of the air; so that they require very few clothes, and in fact go almost quite naked. The only covering of the men consists of two leather straps, which generally hang down the back from the chine to the thighs, each of them in the form of an isosceles triangle, their points uppermost, and fastened to a belt which goes round their waste, their bases not being above three fingers broad; so that the covering they form is extremely trifling. These straps have very little dressing bestowed upon them, so that they make a rattling noise as the Hottentot runs along; and our author supposes that they may produce an agreeable coolness by fanning him. Besides this, the men have a bag or flap made of skin which hangs down before, and is fastened to the belt already mentioned. The hollow part of this seems designed to receive that which with us modesty requires to be concealed; but being only fastened by a small part of its upper end to a narrow belt, in other respects hanging quite loose, it is but a very imperfect concealment; and when the wearer is walking, or otherwise in motion, it is none at all. They call

Hottentots. call this purse by the Dutch name of *jackall*, it being almost always prepared of the skin of that animal, with the hairy side turned outwards.

The women cover themselves much more scrupulously than the men, having always two, and very often three coverings like aprons; though even these seem to be abundantly small for what we would term decency in this country. The outermost of these, which is the largest, measures only from about six inches to a foot in breadth. All of them are made of a skin well prepared and greased, the outermost being adorned with glass beads strung in different figures. The outermost reaches about half-way down the thighs, the middle about a third, or one half less, and the third scarcely exceeds the breadth of the hand. The first is said to be designed for ornament, the second as a defence for modesty, and the third to be useful on certain occasions, which, however, are much less troublesome to the *Hottentot* than to the European females. Our author, with great probability supposes, that it was the sight of this innermost apron which misled the reverend Jesuit Tackard, who, on his return to Europe, first propagated the stories concerning the natural vails or excrescences of the *Hottentots*.—A story was likewise commonly believed, that the men in general had but one testicle, and that such as were not naturally formed in this manner were artificially made so. But this our author likewise denies; and though he says that such an operation might have been formerly performed upon the males, yet it is not so now.

The other garments worn by the *Hottentots* are formed of a sheep's skin with the woolly side turned inwards; this forming a kind of cloak, which is tied forwards over the breast: though sometimes, instead of a sheep's-skin, some smaller kind of fur is used as a material. In warm weather they let this cloak hang carelessly over their shoulders, so that it reaches down to the calves of the legs, leaving the lower part of the breast, stomach, and fore-part of the legs and thighs bare; but in cold weather they wrap it round them; so that the fore-part of the body is likewise pretty well covered by it as far as the knees: But as one sheep-skin is not sufficient for this purpose, they sew on a piece on the top at each side with a thong or catgut. In warm weather they sometimes wear the woolly side outwards, but more frequently take off the cloak altogether, and carry it under their arm. This cloak or *krosse* serves them not only for clothes, but bedding also; and in this they lie on the bare ground, drawing up their bodies so close, that the cloak is abundantly sufficient to cover them.—The cloaks used by the women differ little from these already described, excepting only that they have a long peak on them, which they turn up; forming with it a little hood or pouch, with the hairy side inwards. In this they carry their little children, to which the mother's breasts are now and then thrown over the shoulders; a custom common among some other nations, where the breasts of the females, by continual want of support, grow to an enormous length. The men commonly wear no covering on their heads, though our author says he has seen one or two who wore a greasy night-cap made of skin with the hair taken off. Those who live nearest the colonists have taken a liking to the European hats, and wear them slouched all round, or with only one side turned

up. The women also frequently go bare-headed; though they sometimes wear a cap made in the shape of a short truncated cone. This appears to be the section of some animal's stomach, and is perfectly blacked by soot and fat mixed up together. These caps are frequently prepared in such a manner as to look shaggy; others have the appearance of velvet; and in our author's appearance are not inelegant. Over this they sometimes wear an oval wreath or kind of crown made of a buffalo's hide, with the hair outermost. It is about four fingers breadth in height, and surrounds the head so as to go a little way down upon the forehead, and the same depth on the neck behind, without covering the upper part of the cap above described. The edges of this wreath, both upper and under, are always smooth and even; each of them set with a row of small shells of the *cyprea* kind, to the number of more than 30, in such a manner, that, being placed quite close to one another, their beautiful white enamel, together with their mouths, are turned outwards. Between two rows of these shells run two others parallel, or else waved and indented in various ways. The *Hottentots* never adorn their ears or noses as other savages do: though the latter are sometimes marked with a black streak of soot; at others, though more rarely, with a large spot of red lead; of which last, on festivals and holidays, they likewise put a little on their cheeks. The necks of the men are bare, but those of the women are ornamented with a thong of undressed leather, upon which are strung eight or ten shells. These, which are about the size of beans, have a white ground, with large black spots of different sizes: but as they are always made use of in a burnished state, the Doctor is uncertain whether they be of that kind which is received in the *Systema Naturæ* under the name of *nerita albicilla*, or *exuvia*. These shells are sold at an enormous price, no less than a sheep for each; as it is said that they come from the most distant coast of Caffraria. Both men and women are very fond of European beads, particularly the blue and white ones of the size of a pea; of which they tie several rows round the middle, and next to the girdles which hold the coverings above mentioned. Besides these ornaments, they use rings on their arms and legs; most of them made of thick leather straps generally cut in a circular shape; which, by being beat and held over the fire, are rendered tough enough to retain the curvature that is given them. From these rings it has been almost universally believed, that the *Hottentots* wrap guts about their legs in order to eat them occasionally. The men wear from one to five or six of these rings on their arms, just above the wrist, but seldom on their legs. The matrons of a higher rank have frequently a considerable number of them both on their arms and legs, especially on the latter; so that they are covered with them from the feet up to the knees. These rings are of various thickneses, from that of a goose-quill to two or three times that size. Sometimes they are made of pieces of leather forming one entire ring; so that the arms and feet must be put through them when the wearer wishes to put them on. They are strung upon the legs, small and great, without any nicety; but are so large, that they shake and get twisted when the person walks. Rings of iron or copper, but especially of brass, of the size of a goose.

Hottentots. goose-quill, are considered as more genteel than those of leather. However, they are sometimes worn along with the latter, to the number of six or eight at a time, particularly on the arms. The girls are not allowed to use any rings till they are marriageable. The Hottentots seldom wear any shoes; but such as they do make use of are of the same form with those worn by the African peasants, by the Esthonians, and Livonians, as well as by some Finlanders; so that it is impossible to say whether they are the invention of the Dutch or the Hottentots themselves. They are made of undressed leather, with the hairy side outward; without any other preparation than that of being beat and moistened. If it be a thick and stout hide, as that of a buffalo, it is kept for some hours in cow-dung, which renders it besides very soft and pliable. Some kind of grease is afterwards used for the same purpose. The shoes are then made in the following manner. They take a piece of leather, of a rectangular form, something longer and broader than the foot of the person for whom the shoes are intended; the two foremost corners are doubled up together, and sewed down, so as to cover the fore-part of the foot; but this seam may be avoided, and the shoes made much neater at the toes, by fitting immediately over them a cap taken from the membrane in the knee-joint of the hind-leg of some animal. In order to make this piece of skin or leather rise up to the height of an inch on both sides of the foot, and close it in neatly, it is pierced with holes at small distances all round the edge, as far as the hind-quarters; and through these holes is passed a thong, by which the rim is drawn up into gathers. In order to make strong hind quarters, the back part of the piece of leather is doubled inwards, and then raised up and pressed along the heel. The ends of the thong or gathering string are then threaded on both sides through the upper edge of the hind-quarters, to the height of about two inches; they are then carried forwards, in order to be drawn through two of the above-mentioned holes on the inside of each rim. Lastly, they are tied over the instep, or if it be thought necessary to tie the shoe still faster, they are carried cross-ways over the instep, and so downwards under the thong, which comes out from the hind-quarters; then upwards again over the ankle, and even round the leg itself if the wearer chooses. Shoes of this kind are not without their advantages: they fit as neat upon the foot as a stocking, and at the same time preserve their form. They are easily kept soft and pliable by constantly wearing them; or, if at any time they should become somewhat hard, this is easily remedied by beating and greasing them. They are extremely light and cool, by reason that they do not cover so much of the foot as a common shoe. They wear very well, as they are without any seam, and the soles of the shoes are both tough and yielding. These field shoes, as they are called, being made of almost raw leather, are much more durable than those of tanned leather, which are burnt up by the African sands, and slip and roll about in them; being also very ready to be torn in a rocky soil, which is not the case with the others. The Doctor is of opinion, that these shoes would be particularly useful to sailors.

The huts of the Hottentots are built exactly alike; and we may readily give credit to our author when he

tells us, that they are done in a style of architecture which does not a little contribute to keep envy from insinuating itself under their roofs. Some of these huts are circular, and others of an oblong shape, resembling a round bee-hive or vault; the ground-plot being from 18 to 24 feet in diameter. The highest are so low, that it is scarce ever possible for a middle-sized man to stand upright even in the centre of the arch; "but (says our author) neither the lowness thereof, nor that of the door, which is but just three feet high, can perhaps be considered as any inconvenience to an Hottentot, who finds no difficulty in stooping and crawling upon all fours, and is at any time more inclined to lie down than to stand. The fire-place is in the middle of each hut, by which means the walls are not so much exposed to danger from fire. From this situation of the fire-place also the Hottentots derive this additional advantage, that they can all sit or lie in a circle round it, enjoying equally the warmth of the fire. The door, low as it is, alone lets in day-light or lets out the smoke: and so much are these people accustomed to live in such smoky mansions, that their eyes are never affected by it in the least, nor even by the mephitic vapour of the fuel, which to Europeans would be certain death.

The frame of the arched roof is composed of slender rods or sprays of trees. These being previously bent into a proper form, are laid, either whole or pieced, some parallel to one another, others crosswise; after which they are strengthened by binding others round them in a circular form with withies. All these are taken principally from the *cliffortia conoides*, which grows plentifully in this country near the rivers. Large mats are then placed very neatly over this lattice work, so as perfectly to cover the whole. The aperture which is left for the door is closed occasionally by a skin or piece of matting. These mats are made of a kind of kane or reed in the following manner. The reeds being laid parallel to one another, are fastened together with sinews or catgut, or some kind of catgut which they have had an opportunity of getting from the Europeans; so that they have it in their power to make them as long as they please, and as broad as the length of the reeds, which is from six to ten feet. The colonists make use of the same kind of matting; next to the tilts of their waggons, to prevent the sail-cloth from being rubbed and worn, and likewise to help to keep out the rain.

In a *craal*, or Hottentot village, the huts are most commonly disposed in a circle, with the doors inwards; by which means a kind of court-yard is formed, where the cattle are kept at nights. The milk, as soon as taken from the cow, is put to other milk which is curdled, and kept in a leather sack with the hairy side inwards as being the more cleanly; so that thus the milk is never drunk sweet. In some northern districts, where the land is dry and parched, both Hottentots and colonists are shepherds. When an Hottentot has a mind to shift his dwelling, he lays all the mats, skins, and rods, of which it is composed, on the backs of his cattle, which, to a stranger, makes a monstrous, unwieldy, and even ridiculous appearance.

There is a species of Hottentots named *Bosjesmen*, who dwell in the woody and mountainous parts, and subsist entirely by plunder. They use poisoned ar-

rows,

Hottentots. rows, which they shoot from bows about a yard long and an inch in thickness in the middle, very much pointed at both ends. Dr Sparrman does not know the wood of which they are made, but thinks that it is not very elastic. The strings were made, some of sinews, and others of a kind of hemp, or the inner bark of some vegetable; but most of them in a very slovenly manner. The arrows are about a foot and an half long, headed with bone, and a triangular bit of iron; having also a piece of quill bound on very strongly with sinews, about an inch and an half from the top, in order to prevent it from being easily drawn out of the flesh. The whole is lastly covered over with a very deadly poison of the consistence of an extract. Their quivers are two feet long and four inches in diameter; and are supposed by our author to be made of the branch of a tree hollowed out, or more probably of the bark of one of the branches taken off whole, the bottom and cover being made of leather. It is daubed on the outside with an unctuous substance which grows hard when dry, and is lined about the aperture with the skin of the yellow serpent, supposed to be the most deadly in all that part of the world. The poison they make use of is taken from the most venomous serpents; and, ignorant as the Hottentots are, they all know that the poison of serpents may be swallowed with safety. See the article BOSHIESMEN.

In the year 1779, Lieutenant William Paterson, who took a long and dangerous excursion from the Cape along the western side of the continent, discovered a new tribe of Hottentots, whose living, he says, is in the highest degree wretched, and who are apparently the dirtiest of all the Hottentot tribes. Their dress is composed of the skins of seals and jackals, the flesh of which animals they feed upon. If a grampus happen to be cast ashore, they remove their huts to the place, and feed upon the carcase as long as it lasts, though perhaps it may be half rotten by the heat of the weather. They besmear their skins with the oil; by which means they smell so exceedingly rank that their approach may be thus perceived before they come in sight. Their huts, however, are much superior to those of the southern Hottentots already described; being higher, thatched with grass, and furnished with stools made of the back-bones of the grampus. They dry their fish in the sun; as the lieutenant found several kinds of fish near their huts suspended from poles, probably for this purpose. He found also several aromatic plants which they had been drying.

With respect to the religion of the Hottentots, it does not appear that they have any. On being questioned on the subject of a Creator and Governor of the universe, they answer that they know nothing of the matter; nor do they seem willing to receive any instruction. All of them, however, have the most firm belief in the powers of magic; from whence it might be inferred that they believe in an evil being analogous to what we call *the devil*; but they pay no religious worship to him, though from this source they derive all the evil that happens, and among these evils they reckon cold, rain, and thunder. So monstrously ignorant are they, that many of the colonists assured Dr Sparrman, that their Boshiesmen would abuse the

Nº 158.

thunder with many opprobrious epithets, and threaten Hottentots to assault the flashes of lightning with old shoes, or any thing that comes first to hand. Even the most intelligent among them could not be convinced by all the arguments our author could use, that rain was not always an evil, and that it would be an unhappy circumstance if it were never to rain. "A maxim (says he), from a race of men in other respects really endowed with some sense, and frequently with no small degree of penetration and cunning, ought, methinks, to be considered as an indelible religious or superstitious notion entertained by them from their infancy, rather than as an idea taken up on due deliberation and consequent conviction."

As the Hottentots have so strong a belief in the powers of magic, it is no wonder that they have abundance of witches and conjurers among them. These will readily undertake any thing, even to put a stop to thunder and rain, provided they be well paid for their pains; and if it happen to thunder or rain longer than the time they promised, they have always for an excuse, that a more powerful conjurer has put a stop to their incantations. Many of the Hottentots believe that all disorders incident to the human body are cured by magic. The wizards are fond of encouraging this idea; but at the same time take care to employ both external and internal remedies. Among the former may be reckoned a cure performed upon Captain Cook in some of the South-Sea islands, viz. that of pinching, cuffing, and kneading the whole body of the patient. To this, however, the Hottentot physicians add that of pretending to suck out a bone from some part of the patient's body. After this it sometimes happens that the sick person is relieved, and sometimes not. In the latter case the operation is repeated; and, if he dies, his friends lament that he was bewitched beyond the power of any one to assist him. These conjurers appear to be possessed of considerable slight of hand. Our author was informed by a colonist, that when he was a child, and playing with a bone of an ox which he drew as a cart, it appeared to his great astonishment to be sucked out of a sick person's back by a wizard; and as far as he could remember, the patient recovered soon after. These pretensions of the wizards sometimes render them liable to persecutions; and there is an instance of a chief named *Paloo*, who ordered a general massacre among them, in hopes of cutting off the person who he believed had bewitched himself, and afflicted him with sore eyes.

The superstition of the Hottentots never operates in the way of making them afraid in the dark. They seem, however, to have some ideas of a future state, as they reproach their friends, when dead, with leaving them so soon; at the same time admonishing them from henceforth to demean themselves properly: by which they mean, that their deceased friends should not come back again and haunt them, nor allow themselves to be made use of by wizards to bring any mischief on those that survive them.

There is a genus of insects (the *mantis*) which, it has been generally thought, the Hottentots worship; but our author is so far from being of this opinion, that he tells us they have more than once caught several of them for him, and assisted him in sticking pins through

Hottentots through them as he did through other insects. "There is (says he), however, a diminutive species of this insect, which some think it would be a crime, as well as very dangerous, to do any harm to: but this we have no more reason to look upon as any kind of religious worship, than we have to consider in the same light a certain superstitious notion prevalent among many of the more simple people in our own country (Sweden), who imagine that three sins will be forgiven them, if they set a cock-chaffer on its feet that has happened to fall upon its back. The moon, according to Kolbe, receives a kind of adoration from the Hottentots; but the fact is, that they merely take the opportunity of her beams, and at the same time of the coolness of the night, to amuse themselves with dancing; and consequently have no more thoughts of worshipping her than the Christian colonists who are seen at that time strolling in great numbers about the streets, and parading on the stone steps with which their houses are usually encircled." The conjurors themselves, according to our author, are generally freethinkers, who have neither religion nor superstition of any kind.

Lieutenant Paterfon has given the following account of the Caffres, a nation whom no European but himself has ever seen, and who inhabit the country to the northeast of the Cape as far down as 31° South Latitude.

The men are from five feet ten inches to six feet high, and well proportioned; and in general manifest great courage in attacking lions or other wild beasts. The nation, at the time he visited them, was divided into two parties, one to the northward, commanded by a chief named *Chatha Bea*, or *Tambushie*, which latter appellation he had obtained from his mother, a woman of an Hottentot tribe named *Tambukies*. This man was the son of a chief named *Pharao*, who died about three years before, and left two sons *Cha Cha Bea*, and another named *Dsrika*, who claimed the supreme authority on account of his mother being of the Caffre nation. This occasioned a contest between the two brothers, in the course of which *Cha Cha Bea* was driven out of his territories with a great number of his party; after which he took up his residence at a place named *Khouta*, where he had an opportunity of entering into an alliance with the Boshies-men.—The Caffres are of a jet black colour, their eyes large, and their teeth as white as ivory. The clothing of both sexes is nearly the same; consisting entirely of the hides of oxen, which are made as pliant as cloth. The men wear tails of different animals tied round their thighs, pieces of brass in their hair, and large rings of ivory on their arms: they are likewise adorned with the hair of lions, feathers fastened on their heads, &c. They use the ceremony of circumcision, which is usually performed upon them when they are nine years of age. They are very fond of dogs, which they exchange for cattle, and will even give two bullocks in exchange for one dog which pleases them. They are expert in throwing lances, and in time of war use shields made of the hides of oxen. Throughout the day the men occupy themselves in hunting, fighting, or dancing; the women being employed in the cultivation of their gardens and corn. They seem not to be destitute of the knowledge of agriculture, as they cultivate several vegetables which do not natu-

VOL. VIII. Part II.

rally grow in their own country, viz. tobacco, water-melons, a small kind of kidney-beans, and hemp. The women also make their baskets and the mats on which they lie. The men are very fond of their cattle, and cut their horns in such a manner as to be able to turn them into any shape they please, and teach them to answer to a whistle. Mr Paterfon is of opinion that the country they inhabit is greatly superior to any part of Africa.

Of the Dutch settlements and policy at the Cape, Mr Forster gives the following account.

"The income of the governor here is very considerable; for, besides a fixed appointment, and the use of houses, gardens, proper furniture, and every thing that belongs to his table, he receives about 10 dollars for every league of wine which the company buy of the farmer in order to be exported to Batavia. The company allows the sum of 40 dollars for each league, of which the farmer receives but 24: what remains is shared between the governor and second or deputy; the former taking two-thirds, which sometimes are said to amount to 4000 dollars per annum. The deputy-governor has the direction of the company's whole commerce here, and signs all orders to the different departments under him, as well as the governor to others. He and the fiscal have the rank of *upper koopman*. The fiscal is at the head of the police, and sees the penal laws put in execution: his income consists of fines, and of the duties laid on certain articles of commerce; but if he be strict in exacting them, he is universally detested. The sound policy of the Dutch has likewise found it necessary to place the fiscal as a check, to overawe the other officers of the company, that they may not counteract the interests of their masters, or infringe the laws of the mother-country. He is, to that end, commonly well versed in juridical affairs, and depends solely upon the mother-country. The major (at present Mr Von Prehn, who received us with great politeness) has the rank of *koopman* or merchant: this circumstance surprises a stranger, who, in all other European states, is used to see military honours confer distinction and precedence; and appears still more singular to one who knows the contrast in this particular between Holland and Russia, where the idea of military rank is annexed to every place, even that of a professor at the university. The number of regular soldiers at this colony amounts to about 700; of which 400 form the garrison of the fort, near the Cape-town. The inhabitants capable of bearing arms form a militia of 4000 men; of whom a considerable part may be assembled in a few hours, by means of signals made from alarm-places in different parts of the country. We may from hence make some estimate of the number of white people in this colony, which is at present so extensive, that the distant settlements are above a month's journey from the Cape: but these remote parts lie sometimes more than a day's journey from each other, are surrounded by various nations of Hottentots, and too frequently feel the want of protection from their own government at that distance. The slaves in this colony are at least in the proportion of five or more to one white person. The principal inhabitants at the Cape have sometimes from 20 to 30 slaves, which are in general treated with great lenity,

Hottentots. and sometimes become great favourites with their masters, who give them very good cloathing, but oblige them to wear neither shoes nor stockings, reserving these articles to themselves. The slaves are chiefly brought from Madagascar, and a little vessel annually goes from the Cape thither on that trade; there are, however, besides them, a number of Malays and Bengalese, and some negroes. The colonists themselves are for the greatest part Germans, with some families of Dutch, and some of French Protestants. The character of the inhabitants of the town is mixed. They are industrious, but fond of good living, hospitable, and social; though accustomed to hire their apartments to strangers for the time they touch at this settlement, and used to be complimented with rich presents of stuffs, &c. by the officers of merchant ships. They have no great opportunities of acquiring knowledge, there being no public schools of note at the Cape; their young men are therefore commonly sent to Holland for improvement, and their female education is too much neglected. A kind of dislike to reading, and the want of public amusements, make their conversation uninteresting, and too frequently turn it upon scandal, which is commonly carried to a degree of inveteracy peculiar to little towns. The French, English, Portuguese, and Malay languages, are very commonly spoken, and many of the ladies have acquired them. This circumstance, together with the accomplishments of singing, dancing, and playing a tune on the lute, frequently united in an agreeable person, make amends for the want of refined manners and delicacy of sentiment. There are, however, among the principal inhabitants, persons of both sexes, whose whole deportment, extensive reading, and well-cultivated understanding, would be admired and distinguished even in Europe. Their circumstances are in general easy, and very often affluent, on account of the cheap rate at which the necessaries of life are to be procured: but they seldom amass such prodigious riches here as at Batavia; and I was told the greatest private fortune at the Cape did not exceed 100,000 dollars, or about 22,500 l. sterling.

“ The farmers in the country are very plain hospitable people; but those who dwell in the remotest settlements seldom come to town, and are said to be very ignorant: This may easily be conceived, because they have no better company than Hottentots, their dwellings being often several days journey asunder, which must in a great measure preclude all intercourse. The vine is cultivated in plantations within the compass of a few days journey from the town; which were established by the first colonists, and of which the ground was given in perpetual property to them and their heirs. The company at present never part with the property of the ground, but let the surface to the farmer for an annual rent, which, though extremely moderate, being only 25 dollars for 60 acres, yet does not give sufficient encouragement to plant vineyards. The distant settlements, therefore, chiefly raise corn and rear cattle; nay, many of the settlers entirely follow the latter branch of rustic employment, and some have very numerous flocks. We were told there were two farmers who had each 15,000 sheep, and oxen in proportion; and several who possessed 6000 or 8000 sheep, of which they drive great droves to

town every year: but lions and buffaloes, and the fatigues of the journey, destroy numbers of their cattle before they can bring them so far. They commonly take their families with them in large waggons covered with linen or leather, spread over hoops, and drawn by 8, 10, and sometimes 12 pair of oxen. They bring butter, mutton-tallow, the flesh and skins of sea-cows (hippopotamus), together with lion and rhinoceros' skins to sell. They have several slaves, and commonly engage in their service several Hottentots of the poorer sort, and (as we were told) of the tribe called *BOSHIESMEN*, *Boschemans*, or *Busbmans*, who have no cattle of their own, but commonly subsist by hunting, or by committing depredations on their neighbours. The opulent farmers set up a young beginner by intrusting to his care a flock of 400 or 500 sheep, which he leads to a distant spot, where he finds plenty of good grass and water; the one-half of all the lambs which are yearned fall to his share, by which means he soon becomes as rich as his benefactor.

“ Though the Dutch company seem evidently to discourage all new settlers, by granting no lands in private property; yet the products of the country have of late years sufficed not only to supply the isles of France and Bourbon with corn, but likewise to furnish the mother-country with several ship-loads. These exports would certainly be made at an easier rate than at present, if the settlements did not extend so far into the country, from whence the products must be brought to the Table-bay by land-carriage, on roads which are almost impassable. The intermediate spaces of uncultivated land between the different settlements are very extensive, and contain many spots fit for agriculture; but one of the chief reasons why the colonists are so much divided and scattered throughout the country, is to be met with in another regulation of the company, which forbids every new settler to establish himself within a mile of another. It is evident, that if this settlement were in the hands of the commonwealth, it would have attained to a great population, and a degree of opulence and splendor of which it has not the least hopes at present: but a private company of East-India merchants find their account much better in keeping all the landed property to themselves, and tying down the colonist, lest he should become too great and powerful.

“ The wines made at the Cape are of the greatest variety possible. The best, which is made at M. Vander Spy's plantation of Constantia, is spoken of in Europe, more by report than from real knowledge; 30 leagues (or pipes) at the utmost are annually raised of this kind, and each league sells for about 50 l. on the spot. The vines from which it is made were originally brought from Shiraz in Persia. Several other sorts grow in the neighbourhood of that plantation, which produce a sweet rich wine, that generally passes for genuine Constantia in Europe. French plants of burgundy, muscade, and frontignan, have likewise been tried, and have succeeded extremely well, sometimes producing wines superior to those of the original soil. An excellent dry wine, which has a slight agreeable tartness, is commonly drank in the principal families, and is made of Madeira vines transplanted to the Cape. Several low sorts, not entirely disagreeable, are raised in great plenty, and sold at a very cheap rate; so that the

Hottinger the sailors of the East-India ships commonly indulge themselves very plentifully in them whenever they come ashore.

Hovedon.

“The products of the country supply with provisions the ships of all nations which touch at the Cape. Corn, flour, biscuit, salted beef, brandy, and wine, are to be had in abundance, and at moderate prices; and their fresh greens, fine fruits, good mutton and beef, are excellent restoratives to seamen who have made a long voyage.”

HOTTINGER (John Henry), born at Zurich in Switzerland in 1620, professed the Oriental languages at Leyden, and was esteemed by all his learned colleagues. He was drowned, with part of his family, in the river Lemit, in the year 1667. He wrote a prodigious number of works; the principal of which are, 1. *Exercitationes Anti-Moriniana de Pentateucho Samaritano*, 4to; in which he defends the Hebrew text against father Morin. 2. *Historia Orientalis*, 4to. 3. *Bibliothecarius quadripartitus*. 4. *Thesaurus Philologicus Sacra Scriptura*, 4to. 5. *Historia Ecclesiastica*. 6. *Promptuarium, sive Bibliotheca Orientalis*, 4to. 7. *Dissertationes miscellaneæ*, &c.

HOTTONIA, WATER-VIOLET: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 21st order, *Precia*. The corolla is salver-shaped; the stamina are placed in the tube of the corolla; and the capsule is unilocular. There is but one species, viz. the palustris, with a naked stalk. It grows naturally in the standing waters in many parts of England. The leaves, which are for the most part immersed in water, are finely winged and flat like most of the sea-plants; and at the bottom have long fibrous roots, which strike into the mud: the flower-stalks rise five or six inches above the water, and toward the top have two or three whorls of purple flowers, terminated by a small cluster of the same. These flowers have the appearance of those of the stock-gilliflower, so make a pretty appearance on the surface of the water. It may be propagated in deep standing waters, by procuring its seeds when they are ripe, from the places of their natural growth; which should be immediately dropped into the water in those places where they are designed to grow, and the spring following they will appear; and if they are not disturbed, they will soon propagate themselves in great plenty.—Cows eat this plant; swine refuse it.

HOUBRAKEN (Jacob), a celebrated engraver, whose great excellence consisted in the portrait line. His works are distinguished by an admirable softness and delicacy of execution, joined with good drawing, and a fine taste. If his best performances have ever been surpassed, it is in the masterly determination of the features, which we find in the works of Nanteuil, Edelinck, and Drevet: this gives an animation to the countenance, more easily to be felt than described. His works are pretty numerous; and most of them being for English publications, they are sufficiently known in this country. In particular the greater and best part of the collection of portraits of Illustrious men, published in London by I. and P. Knapton, were by his hand.

HOVEDON (Roger de), born of an illustrious family in Yorkshire, most probably at the town of that name, now called *Howden*, some time in the reign of Henry I. After he had received the first parts of edu-

cation in his native country, he studied the civil and canon law, which were then become most fashionable and lucrative branches of learning. He became domestic chaplain to Henry II. who employed him to transact several ecclesiastical affairs; in which he acquitted himself with honour. But his most meritorious work was his annals of England, from A. D. 731, when Bede's ecclesiastical history ends, to A. D. 1202. This work, which is one of the most voluminous of our ancient histories, is more valuable for the sincerity with which it is written, and the great variety of facts which it contains, than for the beauty of its style, or the regularity of its arrangement.

HOUGH, **HAM**, in the manege, the joint of the hind-leg of a beast, which connects the thigh to the leg. See **HAM**.

To **HOUGH**, or cut the *Houghs*, is to ham-string, or to disable by cutting the sinews of the ham.

HOULIERES (Antoinette de), a French lady, whose poetry is highly esteemed in France. Her works and those of her daughter have been collected and printed together in two volumes. Most of the Idyls, particularly those on sheep and birds, surpass every thing of the kind in the French language: the thoughts and expressions are noble; and the style pure, flowing, and chaste. Mademoiselle des Houlières carried the poetic prize in the French academy against Fontenelle. Both of these ladies were members of the academy of Ricovatri; the mother was also a member of the academy of Arles. Those who desire to be more particularly acquainted with the history of Madam des Houlières, may consult her life prefixed to her works in the Paris edition of 1747, 2 vols 12mo.

HOULSWORTHY, a large town of Devonshire, seated between two branches of the river Tamer, having a good market for corn and provisions. W. Long. 4. 42. N. Lat. 50. 50.

HOUND. See *CANIS*, *BLOOD-Hound*, and *GRE-Hound*.

Training of HOUNDS. Before we speak of the methods proper to be used for this purpose, it will be necessary to point out the qualities which sportsmen desire to meet with in these animals. It is generally understood, that hounds of the middle size are the most proper, it being remarked, that all animals of that description are stronger than either such as are very small or very large. The shape of the hound ought to be particularly attended to; for if he be not well proportioned, he can neither run fast nor do much work. His legs ought to be straight, his feet round, and not very large; his shoulders back; his breast rather wide than narrow; his chest deep, his back broad, his head small, his neck thin; his tail thick and bushy, and if he carry it well so much the better. None of those young hounds which are *out at the elbows*, or such as are weak from the knee to the foot, should ever be taken into the pack. That the pack may look well, it is proper that the hounds should be as much as possible of a size: and if the animals be handsome at the same time, the pack will then be perfect. It must not, however, be thought, that this contributes any thing to the *goodness* of a pack; for very unhandsome packs, consisting of hounds entirely different in size and colour, have been known to afford very good sport. It is only necessary that they should run well together; to which indeed an uniformity in

Hough
||
Hound.

Hound.

size and shape would seem to contribute in some degree. The pack that can run ten miles, or any other considerable space, in the shortest time, may be said to go fastest, though the hounds taken separately might be considerably inferior to others in swiftness. A pack of hounds, considered in a collective body, go fast in proportion to the excellence of their noses and the head they carry. Packs which are composed of hounds of various kinds seldom run well. When the packs are very large, the hounds are seldom sufficiently hunted to be good; twenty or thirty couple, therefore, or at most forty, will be abundantly sufficient for the keenest sportsman in this country, as thus he may be enabled to hunt three or even four times a week. The number of hounds to be kept, must, however, in a considerable degree, depend on the strength of the pack and the country in which you hunt. They should be left at home as seldom as possible; and too many old hounds should not be kept. None ought to be kept above five or six seasons, though this also is somewhat uncertain, as we have no rule for judging how long a hound will last.

In breeding of hounds, considerable attention ought to be paid to the dog from whom you breed. All such are to be rejected as have a tender nose, as are *babblers* or *skirters*. An old dog should never be put to an old bitch; nor should any attempts be made to cross the breed unless in a proper and judicious manner. Mr Beckford † informs us, that he has seen fox-hounds bred out of a Newfoundland dog and fox-hound bitch; the whelps were monstrously ugly, and had other bad qualities besides. The cross most likely to be of service to a fox-hound is the beagle. The reason of crossing the breeds sometimes is, that the imperfections of one may sometimes be remedied by another. The months of January, February, and March, are the best for breeding; late puppies seldom thrive. After the females begin to grow big with young, it will not be proper to let them hunt any more, or indeed to remain for a much longer time in the kennel. Sometimes these animals will have an extraordinary number of whelps. Mr Beckford informs us, that he has known a bitch have 15 puppies at a litter; and he assures us, that a friend of his informed him, that a hound in his pack brought forth 16, all of them alive. In these cases it is proper to put some of the puppies to another bitch, if you want to keep them all; but if any are destroyed, the best coloured ought to be kept. The bitches should not only have plenty of flesh, but milk also; and the puppies should not be taken from them till they are able to take care of themselves: their mothers will be relieved when they learn to lap milk, which they will do in a short time. After the puppies are taken away from their mothers, the litter should have three purging balls given them, one every other morning, and plenty of whey the intermediate day. If a bitch bring only one or two puppies, and you have another that will take them, by putting the puppies to her the former will soon be fit to hunt again. She should, however, be first physicked, and it will also be of service to anoint her dugs with brandy and water.

Whelps are very liable to the distemper to which dogs in general are subject, and which frequently makes great havoc among them at their walks; and this is supposed by Mr Beckford to be owing to the

little care that is taken of them. "If the distemper (says he) once get among them, they must all have it: yet notwithstanding that, as they will be constantly well fed, and will lie warm (in a kennel built on purpose), I am confident it would be the saving of many lives. If you should adopt this method, you must remember to use them early to go in couples: and when they become of a proper age, they must be walked out often; for should they remain confined, they would neither have the health, shape, or understanding, which they ought to have. When I kept harriers, I bred up some of the puppies at a distant kennel; but having no servants there to exercise them properly, I found them much inferior to such of their brethren as had the luck to survive the many difficulties and dangers they had undergone at their walks; these were afterwards equal to any thing, and afraid of nothing; whilst those that had been nursed with so much care, were weakly, timid, and had every disadvantage attending private education. I have often heard as an excuse for hounds not hunting a cold scent, that they were too *high-bred*. I confess I know not what that means: but this I know, that hounds are frequently too *ill-bred* to be of any service. It is judgment in the breeder, and patience afterwards in the huntsman, that makes them hunt.

"When young hounds are first taken in, they should be kept separate from the pack; and as it will happen at a time of the year when there is little or no hunting, you may easily give them up one of the kennels and grass court adjoining. Their play frequently ends in a battle; it therefore is less dangerous where all are equally matched.—If you find that they take a dislike to any particular hound, the safest way will be to remove him, or it is probable they will kill him at last. When a feeder hears the hounds quarrel in the kennel, he halloos to them to stop them; he then goes in among them, and flogs every hound he can come near. How much more reasonable, as well as efficacious, would it be, were he to see which were the combatants before he speaks to them. Punishment would then fall, as it ought, on the guilty only. In all packs there are some hounds more quarrelsome than the rest; and it is to them we owe all the mischief that is done. If you find chastisement cannot quiet them, it may be prudent to break their holders; for since they are not necessary to them for the meat they have to eat, they are not likely to serve them in any good purpose. Young hounds should be fed twice a day, as they seldom take kindly to the kennel meat at first, and the distemper is most apt to seize them at this time. It is better not to round them till they are thoroughly settled; nor should it be put off till the hot weather, for then they would bleed too much. It may be better perhaps to round them at their quarters, when about six months old; should it be done sooner, it would make their ears tuck up. The tailing of them is usually done before they are put out; it might be better, perhaps, to leave it till they are taken in. Dogs must not be rounded at the time they have the distemper upon them, as the loss of blood would weaken them too much.

"If any of the dogs be thin over the back, or any more quarrelsome than the rest, it will be of use to cut them: I also spay such bitches as I shall not want to breed from; they are more useful, are stouter, and are

† Essay on Hunting.

Hound. are always in better order; besides it is absolutely necessary if you hunt late in the spring, or your pack will be very short for want of it. The latter operation, however, does not always succeed; it will be necessary therefore to employ a skilful person, and one on whom you can depend; for if it be ill done, though they cannot have puppies, they will go to heat notwithstanding. They should be kept low for several days before the operation is performed, and must be fed on thin meat for some time after."

It is impossible to determine how many young hounds ought to be bred in order to keep up the pack, as this depends altogether on contingencies. The deficiencies of one year must be supplied by the next; but it is probable, that from 30 to 35 couple of old hounds, and from eight to twelve couple of young ones, will answer the purpose where no more than 40 couple are to be kept. A considerable number, however, ought always to be bred; for it is undoubtedly, and evidently true, that those who breed the greatest number of hounds must expect the best pack.

After the hounds have been rounded, become acquainted with the huntsman, and answer to their names, they ought to be coupled together, and walked out among sheep. Such as are particularly ill natured ought to have their couples loose about their necks in the kennel till they become reconciled to them. The most stubborn ought to be coupled to old hounds rather than to young ones; and two dogs should not be coupled together when you can avoid it. As young hounds are awkward at first, a few ought only to be set out at a time with people on foot, and they will soon afterwards follow a horse. When they have been walked out often in this manner amongst the sheep, they should be uncoupled by a few at a time, and those chastised who offer to run after the sheep; but it will be difficult to reclaim them after they have once been allowed to taste blood. Some are accustomed to couple the dogs with a ram in order to break them from sheep; but this is very dangerous for both parties. Mr Beckford relates a story of a nobleman who put a large ram into his kennel in order to break his hounds from sheep; but when he came some time after to see how nobly the ram defended himself, he found him entirely eaten up, and the hounds gone to sleep after having filled their bellies.

When hounds are to be aired, it is best to take them out separately, the old ones one day, and the young another; though, if they are to have whey from a distant dairy, both old and young may be taken out together, observing only to take the young hounds in couples, when the old ones are along with them. Young hounds are always apt to fall into mischief, and even old ones when idle will be apt to join them. Mr Beckford mentions a whole pack running after a flock of sheep through the mere accident of a horse's falling, and then running away.

With regard to the first entering of hounds to a scent, our author gives such directions as have subjected him to a severe charge of inhumanity. We shall give them in his own words. "You had better enter them at their own game; it will save you much trouble afterwards. Many dogs, I believe, like that scent best which they were first blooded to: but be this as it may, it is most certainly reasonable to use them to that which it is intended they should hunt. It may

not be amiss first when they begin to hunt to put light collars on them. Young hounds may easily get out of their knowledge; and shy ones, after they have been much beaten, may not choose to return home. Collars, in that case, may prevent their being lost.—You say you like to see your young hounds run a trail-scent.—I have no doubt that you would be glad to see them run over an open down, where you could so easily observe their action and their speed. I cannot think the doing of it once or twice could hurt your hounds; and yet as a sportsman I dare not recommend it to you. All that I can say is, that it would be less bad than entering them at hare. A cat is as good a trail as any; but on no account should any trail be used after your hounds are stooped to a scent. I know an old sportsman who enters his young hounds first at a cat, which he drags along the ground for a mile or two, at the end of which he turns out a badger, first taking care to break his teeth: he takes out about a couple of old hounds along with the young ones to hold them on. He never enters his young hounds but at vermin; for he says, Train up a child in the way he should go, and when he is old he will not depart from it!"

Hounds ought to be entered as soon as possible, though the time must be uncertain, as it depends on the nature of the country in which they are. In corn countries hunting may not be practicable till the corn is cut down; but you may begin sooner in grass countries, and at any time in woodlands. "If (says Mr Beckford) you have plenty of foxes, and can afford to make a sacrifice of some of them for the sake of making your young hounds steady, take them first where you have least riot, putting some of the steadiest of your old hounds among them. If in such a place you are fortunate enough to find a litter of foxes, you may assure yourself you will have but little trouble with your young hounds afterwards.—If, owing to a scarcity of foxes, you should stoop your hounds at hare, let them by no means have the blood of her; nor, for the sake of consistency, give them much encouragement. Hare-hunting has one advantage;—hounds are chiefly in open ground, where you can easily command them; but notwithstanding that, if foxes be in tolerable plenty, keep them to their own game.—Frequent hallooing is of use with young hounds; it keeps them forward, prevents their being lost, and hinders them from hunting after the rest. The oftener therefore that a fox is seen and hallooed, the better. I by no means, however, approve of much hallooing to old hounds; though it is true that there is a time when hallooing is of use, a time when it does hurt, and a time when it is perfectly indifferent: but long practice and great attention to hunting can only teach the application.

"Hounds at their first entrance cannot be encouraged too much. When they are become handy, love a scent, and begin to know what is right, it will then be soon enough to chastise them for what is wrong; in which case one severe beating will save a great deal of trouble. When a hound is flogged, the whipper-in should make use of his voice as well as his whip. If any be very unsteady, it will not be amiss to send them out by themselves when the men go out to exercise their horses. If you have hares in plenty, let some be found sitting, and turned out before them; and you will find that the most riotous will not run after them. If you intend

Hound. tend them to be steady from deer, they should often see deer, and then they will not regard them; and if after a probation of this kind you turn out a cub before them, with some old hounds to lead them on, you may assure yourself they will not be unsteady long."

It is proper to put the young hounds into the pack when they stoop to a scent, become handy, know a rate, and stop easily. A few only are to be put to the pack at a time; and it is not advisable even to begin this till the pack have been out a few times by themselves, and "are gotten well in blood." They should be low in flesh when you begin to hunt; the ground being generally hard at that time, so that they are liable to be shaken.—By hounds being *handy*, our author means their being ready to do whatever is required of them; and particularly, when cast, to turn easily which way the huntsman pleases.

Mr Beckford begins to hunt with his young hounds in August. The huntsman in the preceding months keeps his old hounds healthy by giving them proper exercise, and gets his young hounds forward; and for this purpose nothing answers so well as taking them frequently out. The huntsman should go along with them, get frequently off his horse, and encourage them to come to him:—too much restraint will frequently incline the hounds to be riotous. Our author frequently walks out his hounds among sheep, hares, and deer. Sometimes he turns down a cat before them, which they kill; and when the time of hunting approaches, he turns out young foxes or badgers; taking out some of the most steady of his old hounds to lead on the young ones. Small covers and furze-brakes are drawn with them to use them to a halloo, and to teach them obedience. If they find improper game and hunt it, they are stopped and brought back; and as long as they will stop at a rate, they are not chastised. At such times as they are taken out to air, the huntsman leads them into the country in which they are designed to hunt; by which means they acquire a knowledge of the country, and cannot miss their way home at any time afterwards. When they begin to hunt, they are first brought into a large cover of his own, which has many ridings cut in it; and where young foxes are turned out every year on purpose for them. After they have been hunted for some days in this manner, they are sent to more distant covers, and more old hounds added to them. There they continue to hunt till they are taken into the pack, which is seldom later than the beginning of September; for by that time they will have learned what is required of them, and seldom give much trouble afterwards. In September he begins to hunt in earnest; and after the old hounds have killed a few foxes, the young ones are put into the pack, two or three couple at a time, till all have hunted. They are then divided; and as he seldom has occasion to take in more than nine or ten couple, one half are taken out one day, and the other the next, till they are steady.

To render fox-hunting complete, no young hounds should be taken into the pack the first season;—a requisite too expensive for most sportsmen. The pack should consist of about 40 couple of hounds, that have hunted one, two, three, four, or five seasons. The young pack should consist of about 20 couple of young hounds, and an equal number of old ones. They should have a separate establishment, and the two kennels

should not be too near one another. When the season is over, the best of the young hounds should be taken into the pack, and the draught of old ones exchanged for them. Many must be bred to enable a sportsman to take in 20 couple of young hounds every season. It will always be easy to keep up the number of old hounds; for when your own draft is not sufficient, drafts from other packs may be obtained, and at a small expence. When young hounds are hunted together for the first season, and have not a sufficient number of old ones along with them, it does more harm than good.

Kennel for HOUNDS. See KENNEL.

HOUNSLOW, a town of Middlesex, 10 miles from London. It is situated on a heath of the same name; and belongs to two parishes, the north side of the street to Heston, and the south side to Isleworth. It is situated on the edge of a heath of the same name, and near it are powder-mills. It has fairs on Trinity-Monday, and Monday after September 29. Here is a charity-school and a chapel. In this place was formerly a convent of mendicant friars, who, by their institution, were to beg alms for the ransom of captives taken by the infidels.—The heath is noted for robberies and horse-races.

HOU-QUANG, a province of China, occupying nearly the centre of the empire: the river Yang-tse-kiang traverses it from west to east; and divides it into two parts, the northern and southern. This province (the greater part of which is level, and watered by lakes, canals, and rivers) is celebrated for its fertility; the Chinese call it the store-house of the empire; and it is a common saying among them, that "the abundance of Kiang-si could furnish all China with a breakfast; but the province of Hou-quang alone could supply enough to maintain all its inhabitants." Some princes of the race of Hong-you formerly resided in this province; but that family was entirely destroyed by the Tartars when they conquered China. The people here boast much of their cotton cloths, simples, gold-mines, wax, and paper made of the bamboo-reed. The northern part of the province contains eight *fou*, or cities of the first class, and sixty of the second and third. The southern comprehends seven of the first class, and fifty-four of the second and third, exclusive of forts, towns, and villages, which are every where to be found.

HOUR, in chronology, an aliquot part of a natural day, usually a 24th, but sometimes a 12th. The origin of the word *hora*, or *ωρα*, comes, according to some authors, from a surname of the sun, the father of hours, whom the Egyptians call *Horus*. Others derive it from the Greek *ορίζω*, to terminate, distinguish, &c. Others from the word *ουρον* urine; holding, that Trismegistus was the first that settled the division of hours, which he did from observation of an animal consecrated to Serapis, named *cynocephalus*, which makes water 12 times a-day, and as often in the night, at equal intervals.

An hour, with us, is a measure or quantity of time, equal to a 24th part of the natural day, or nycthemeron; or the duration of the 24th part of the earth's diurnal rotation. Fifteen degrees of the equator answer to an hour; though not precisely, but near enough for common use. It is divided into 60 minutes; the minute into 60 seconds, &c.

Hours

H

Houses.

House.

The division of the day into hours is very ancient : as is shown by Kircher, *Oedipt. Egypt.* Tom. II. P. II. class. VII. c. 8. : though the passages he quotes from Scripture do not prove it.—The most ancient hour is that of the 12th part of the day. Herodotus, lib. ii. observes, that the Greeks learnt from the Egyptians, among other things, the method of dividing the day into twelve parts.—The astronomers of Cathaya, &c. bishop Beveridge observes, still retain this division. They call the hour *chag*; and to each *chag* give a peculiar name, taken from some animal: The first is called *zeth*, “mouse;” the second, *chiu*, “bullock;” the third, *zem*, “leopard;” the fourth, *mau*, “hare;” the fifth, *chiu*, “crocodile, &c.

The division of the day into 24 hours, was not known to the Romans before the first Punic war.—Till that time they only regulated their days by the rising and setting of the sun. They divided the 12 hours of their day into four, viz. *prime*, which commenced at six o'clock; *third*, at nine; *sixth*, at twelve, and *none*, at three. They also divided the night into our watches, each containing three hours.

HOURS, HORÆ, in the ancient mythology, were certain goddesses, the daughters of Jupiter and Themis; at first only three in number, Eunomia, Dice, and Irene; to which were afterwards added two more, Carpo and Thallote.

Homer makes them the doorkeepers of heaven. Ovid allots them the employment of harnessing the sun :

Jungere equos Titan velocibus imperat Horis.

And speaks of them as standing, at equal distances, about the throne of Sol :

—*et, posite spatii equalibus, Horæ.*

The poets represent them as dressed in fine coloured or embroidered robes, and gliding on with a quick and easy motion.

HOURS, *Horæ*, in the Romish church, are certain prayers performed at stated times of the day; as matins, vespers, lauds, &c.—The lesser hours are, *prime*, *terce*, *sixth*, and *none*. They are called *hours*, or *canonical hours*, as being to be rehearsed at certain hours prescribed by the canons of that church, in commemoration of the mysteries accomplished at those hours. These hours were anciently also called *course*, *curfus*; F. Mabillon has a dissertation on them, intitled, *De Curfu Gallicano*.

The first constitution enjoining the observation of the canonical *hours*, is of the ninth century, being found in a capitular of Heito bishop of Basil directed to his curates, importing that the priests shall never be absent at the canonical hours either by day or night.

Hour-Glass, a popular kind of chronometer or clepsydra, serving to measure the flux of time by the descent or running of sand out of one glass vessel into another. The best hour-glasses are those which, instead of sand, have egg-shells well dried in the oven, then beaten fine and sifted.—Hour-glasses are much used at sea for reckoning, &c.

HOURIS, in modern history, is a name given by the Mahometans to those females that are designed for the faithful in paradise. These are not the same with whom they have lived on earth, but formed for this purpose with singular beauty and undecaying charms.

HOUSE, a habitation, or place built with conveniences for dwelling in. See ARCHITECTURE.

Houses, amongst the Jews, Greeks, and Romans,

were flat on the top for them to walk upon, and had usually stairs on the outside, by which they might ascend and descend without coming into the house. Each house, in fact, was so laid out, that it inclosed a quadrangular area or court. This court was exposed to the weather, and being open to the sky, gave light to the house. This was the place where company was received, and for that purpose it was strewn with mats or carpets for their better accommodation. It was paved with marble or other materials, according to the owner's ability, and provided with an umbrella of vellum to shelter them from the heat and inclemencies of the weather. This part of their houses, called by the Romans *impluvium*, or *cava adium*, was provided with channels to carry off the water into the common sewers. The top of the house was level, and covered with a strong plaster by way of terrace. Hither, especially amongst the Jews, it was customary to retire for meditation, private converse, devotion, or the enjoyment of the evening breezes.

The Grecian houses were usually divided into two parts, in which the men and women had distinct mansions assigned. The part assigned to the men was towards the gate, and called *Andronitis*; the apartment of the women was the farthest part of the house, and called *Gynaikitis*. Jews, Greeks, and Romans, supposed their houses to be polluted by dead bodies, and to stand in need of purification.

HOUSE is also used for one of the estates of the kingdom of Britain assembled in parliament. Thus we say, the house of lords, the house of commons, &c. See PEERS, COMMONS, &c.

HOUSE is also used for a noble family, or a race of illustrious persons issued from the same stock. In this sense we say, the house or family of the Stuarts, the Bourbons, the house of Hanover, of Austria, of Lorraine, of Savoy, &c.

Cheap, easy, and expeditious Method of constructing Houses, which have been found to be very useful hospitals for the recovery of the sick, and therefore may probably make very wholesome places of residence for the healthy.—The first thing to be done is to choose a dry and airy situation, on a gravelly or chalky soil if possible; upon this lay down the plan of your building, make one end of it face that quarter from whence the purest and healthiest winds may be expected to blow, of a breadth that can be conveniently roofed. Then, if boarding does not come so cheap, drive stakes, at about six feet distance from each other, into the ground, so as to stand about six feet above it; and, interlacing them with wattles, coat the wattles on the side next the weather with fresh straw; and make the roof in the same manner, but thicker, or of thatch in the usual way, with a hole at the very top of it, to open occasionally. Let the end of the building facing the wholesomest quarter lie open some feet back, so as to form a porch, where the convalescents may take the air without danger of any injury from the weather. A large chimney and kitchen grate may be erected at the other end. If the soil happens to be chalky or gravelly, you may hollow it four or five feet deep, within a foot or eighteen inches of the walls; but let the steps into this hollow lie far enough within the porch, that no water may get into it, and, if of chalk, the steps may not grow slippery in wet weather. From time to time open the vent-hole at the roof; by means

of

House.

of which all the unwholesome infectious air, as being warmer, and consequently lighter, than that which is pure and wholesome, will be driven out by the rushing in of the fresh air: a purpose, which the little openings, that may be left in the sides and roofs of such rude and hasty buildings, will, even of themselves, answer so well, as sufficiently to compensate any cold they may let in, even in the coldest months. Let the floor likewise be scraped three or four inches deep every five or six days, and what comes off removed to some distance. Halls of this kind, 50 feet long and 20 broad, cost but a trifle to build; yet, with these precautions (even without the addition of clean straw for every new patient to lie on, inclosed in clean washed sacks fit for the purpose, which come infinitely cheaper than the bare cleaning of flock or even feather-beds, supposing it possible to wash such beds), proved of infinitely more advantage in the recovery of sick soldiers, than the low-roofed rooms of the farm houses of the Isle of Wight, or even the better accommodations of Carisbrooke castle in the same island, in which there perished four times the number of sick that there did in these temporary receptacles; which were first thought of by doctor Procklesby, on occasion of some terrible infections from confined animal effluvia.

Is it not surprising, that we have not availed ourselves more of the above discovery in natural history, being, perhaps, the most important the moderns can boast of, in the most useful science, viz. the superior lightness of unwholesome and infectious air! The upper sashes in most houses, even of those who pretend to some knowledge in these matters, are generally immovable, by means of which no part of the foul air above the level of the lowest rail of the other sash's greatest rise can escape by the window; and, if it escapes by the doors, it is generally for want of a vent in the highest part of the roof, merely to accumulate in the upper story of the house, and add to the infection, which the great quantities of old furniture usually stored up there are of themselves but too apt to create, when care is not frequently taken to open the windows of it. Thus, the chief benefit to be expected from lofty rooms is in a great measure lost. Whereas, were the upper sashes contrived to come down, all the air might be easily changed, and that almost insensibly, by letting them down an inch or two. Nay, the upper sash might be often let entirely down with less danger or inconvenience from cold, than the lower thrown up the tenth part of an inch, though the doing of the former would be attended with infinitely more advantage to the health of the inhabitants than the latter. It is, perhaps, on this principle, that we are to account for the good health enjoyed by the poor who live crowded in damp cellars, and often with great numbers of rabbits, poultry, and even swine about them. These cellars are open to the street, with doors reaching from the floor to the very ceiling, but never so close at bottom or at top as to prevent a free circulation of air; in consequence of which, that all vivifying fluid, as fast as it is spoiled by passing through the lungs of the inhabitants and their stock, or is infected by their insensible perspiration, excrements, &c. is driven out and replaced by the fresh air.

N^o 158.

HOUSE, in astrology, denotes the twelfth part of the heavens.

The division of the heavens into houses, is founded upon the pretended influence of the stars, when meeting in them, on all sublunary bodies. These influences are supposed to be good or bad; and to each of these houses particular virtues are assigned, on which astrologers prepare and form a judgment of their horoscopes. The horizon and meridian are two circles of the celestial houses, which divide the heavens into four equal parts, each containing three houses; six of which are above the horizon and six below it; and six of these are called *eastern* and six *western houses*.

A scheme or figure of the heavens is composed of 12 triangles, all called *houses*, in which is marked the stars, signs, and planets, so included in each of these circles. Every planet has likewise two particular houses, in which it is pretended that they exert their influence in the strongest manner; but the sun and moon have only one, the house of the former being Leo, and that of the latter Cancer.

The houses in astrology have also names given them according to their qualities. The first is the house of life: this is the ascendant, which extends five degrees above the horizon, and the rest below it. The second is the house of riches: the third, the house of brothers: the fourth, in the lowest part of the heavens, is the house of relations, and the angle of the earth: the fifth, the house of children: the sixth, the house of health: the seventh, the house of marriage, and the angle of the west: the eighth, the house of death: the ninth, the house of piety: the tenth, the house of offices: the eleventh, the house of friends: and the twelfth, the house of enemies.

Country-HOUSE, is the *villa*† of the ancient Romans, the *quinta* of the Spaniards and Portuguese, the *closerie* and *cassine* of the French, and the *vigna* of the Italians.

It ought always to have wood and water near it; these being the principal beauties of a rural seat. The trees make a far better defence than hills, as they yield a cooling and healthy air, shade during the heat of summer, and very much break the severities of the winter season.

It should not be situated too low, on account of the moisture of the air; and, on the other hand, those built on places exposed to the winds are expensive to keep in repair. In houses not above two stories high, and upon a good foundation, the length of two bricks, or 18 inches, for the heading course, will be sufficient for the ground-work of any common structure; and six or seven courses above the earth, to a water-table, where the thickness of the walls are abated or taken in, on either side the thickness of a brick, viz. two inches and a quarter. But for large and high houses of three, four, or five stories, with garrets, their walls ought to be three heading courses of bricks, or 28 inches at least, from the foundation to the first water-table; and at every story a water-table, or taking in, on the inside, for the summers, girders, and joists to rest upon, laid into the middle, or one quarter of the wall at least, for the better bond. But as for the partition-wall, a brick and half will be sufficiently thick; and for the upper stories, a brick length or nine inch brick will suffice.

Hot-House. See STOVE and HYPOCAUSTUM.

HOUSE.

House,
Household.

HOUSE-Breaking, or *Robbing*, is the breaking into and robbing a house in the day-time; the same crime being termed *BURGLARY* when done by night: both are felony without benefit of clergy.

HOUSEHOLD, the whole of a family considered collectively, including the mistress, children, and servants. But the household of a sovereign prince includes only the officers and domestics belonging to his palace.

The principal officers of his majesty's household are, the lord steward, lord chamberlain of the household, the groom of the stole, the master of the great wardrobe, and the master of the horse.

The civil government of the king's house is under the care of the lord steward of the king's household; who, being the chief officer, all his commands are observed and obeyed. His authority extends over all the other officers and servants, except those of his majesty's chapel, chamber, and stable, and he is the judge of all crimes committed either within the court or the verge.

Under him are the treasurer of the household, the comptroller, cofferer, the master of the household, the clerks of the green-cloth, and the officers and servants belonging to the accounting-house, the marshalsea, the verge, the king's kitchen, the household kitchen, the acatery, bake-house, pantry, buttery, cellar, pastry, &c. Next to the lord steward is the lord chamberlain of the household, who has under him the vice-chamberlain, the treasurer, and comptroller of the chamber; 48 gentlemen of the privy chamber, 12 of whom wait quarterly, and two of them lie every night in the privy-chamber; the gentleman usher, the grooms of the great chamber, the pages of the presence-chamber; the mace-bearers, cup-bearers, carvers, musicians, &c. See *LORD CHAMBERLAIN of the Household*.

The groom of the stole has under him the 11 other lords of the bed-chamber, who wait weekly in the bed-chamber, and by turns lie there a-nights on a pallet-bed; and also the grooms of the bed-chamber, the pages of the bed-chamber and back-stairs, &c. See *Groom of the STOLE*.

The master or keeper of the great wardrobe has under him a deputy, comptroller, clerk of the robes, brusher, &c. and a number of tradesmen and artificers, who are all sworn servants to the king.

The master of the horse has under his command the equerries, pages, footmen, grooms, coachmen, farriers, saddlers, and all the other officers and tradesmen employed in his majesty's stables.

Next to the civil list of the king's court, is the military, consisting of the band of gentlemen pensioners, the yeomen of the guard, and the troops of the household; of which the two first guard the king above stairs.

When the king dines in public, he is waited upon at table by his majesty's cup-bearers, carvers, and gentlemen sewers; the musicians playing all the time. The dinner is brought up by the yeomen of the guard, and the gentlemen sewers set the dishes in order. The carvers cut for the king, and the cup-bearers serve him the drink with one knee on the ground, after he has first tasted it in the cover.

HOUSE and Window Duty, a branch of the king's extraordinary revenue*.—As early as the conquest mention is made in domesday book of fumage or fuel.

gage, vulgarly called *smoke-farthings*; which were paid by custom to the king for every chimney in the house. And we read that Edward the Black Prince (soon after his successes in France), in imitation of the English custom, imposed a tax of a florin upon every hearth in his French dominions. But the first parliamentary establishment of it in England was by statute 13 & 14 Car. II. c. 10. whereby an hereditary revenue of 2s. for every hearth, in all houses paying to church and poor, was granted to the king for ever. And, by subsequent statutes, for the more regular assessment of this tax, the constable and two other substantial inhabitants of the parish, to be appointed yearly (or the surveyor appointed by the crown, together with such constable or other public officer), were, once in every year, empowered to view the inside of every house in the parish. But, upon the Revolution, by stat. 1. W. & M. c. 10. hearth-money was declared to be "not only a great oppression to the poorer sort, but a badge of slavery upon the whole people, exposing every man's house to be entered into and searched at pleasure, by persons unknown to him; and therefore, to erect a lasting monument of their majesties goodness, in every house in the kingdom the duty of hearth-money was taken away and abolished." This monument of goodness remains among us to this day: but the prospect of it was somewhat darkened, when in six years afterwards, by statute 7 W. III. c. 18. a tax was laid upon all houses (except cottages) of 2s. now advanced to 3s. per house, and a tax also upon all windows, if they exceeded nine, in such house. Which rates have been from time to time varied, being now extended to all windows exceeding six; and power is given to surveyors, appointed by the crown, to inspect the outside of houses, and also to pass through any house, two days in the year, into any court or yard, to inspect the windows there.

Schemes of the different rates of duty upon houses and windows may be seen in the *Almanacks*, or in *Kearsey's Tax-Tables* published yearly.

HOUSE-Leek, in botany. See *SEDUM* and *SEMPER-VIVUM*.

HOUSING, or *HOUSE-Line*, in the sea-language, a small line, formed of three fine strands or twists of hemp, smaller than rope-yarn. It is chiefly used to seize blocks into their strops, to bind the corners of the sails, or to fasten the bottom of a sail to its bolt-rope, &c. See *BOLT-Rope*.

HOUSING, or *Houfee*, a cover laid over the saddle of a horse, in order to save it from the weather, dirt, &c. The word is formed of the French *houffe*, which signifies the same thing; though it anciently denoted a kind of hood worn by country people.—The cavaliers appeared with their embroidered housings.

HOUSING, among bricklayers, a term used for a brick which is warped, or is cast crooked or hollow in burning; in such a case, they say it is *housing*.

HOUSTONIA, in botany; a genus of the monogynia order, belonging to the tetrandria class of plants; and in the natural method ranking under the 47th order, *Stellata*. The corolla is monopetalous and funnel-shaped; the capsule bilocular, dispermous, superior.

HOU-TCHEOU-FOU, a city of China, in the province of Tche-kiang. It is a city of the first class; and is situated on a lake, from which it takes its name. The quantity of silk manufactured here is almost incredible.

Household
||
Hou-
tcheou-fou.

* See *Revenue*.

Howard. dible. To give some idea of it, we shall only say, that the tribute paid by a city under its jurisdiction, named *Te-tsin-hien*, amounts to more than 500,000 *taëls* or ounces of silver. Its district contains seven cities, one of which is of the second, and six of the third, class.

HOWARD (HENRY), earl of Surry, a soldier and a poet, the son and grandson of two lord treasurers, dukes of Norfolk, was born probably about the year 1520, and educated in Windsor castle, with young Fitzroy earl of Richmond, natural son to king Hen. VIII. Wood says, from tradition, that he was some time a student at Cardinal College, Oxford. In his youth he became enamoured of the Fair Geraldine, whom his sonnets have immortalized. In 1532, Howard with his companion Richmond was at Paris, where they continued some time. The latter died in 1536; after which our young hero made a tour to Italy, and at Florence, like a true *enamorado*, published a challenge against all comers, whether Christians, Jews, Saracens, Turks, or cannibals, in defence of the beauty of his fair Geraldine; and was victorious in the tournament instituted by the grand duke on the occasion. The duke, we are told, was so charmed with his gallant exploits, that he would gladly have retained him at his court; but he rejected the invitation, being determined to maintain the superlative beauty of his Geraldine in all the principal cities in Italy. This romantic resolution was however frustrated by the command of his sovereign, Henry VIII. to return to England.

In 1540, he signalized himself in a tournament at Westminster, against Sir John Dudley, Sir Thomas Seymour, and others. In 1542, he marched, under the command of his father, against the Scots; and in the same year was confined in Windsor castle for eating flesh in Lent, contrary to the king's proclamation. In 1544, on the expedition to Boulogne in France, he was appointed field-marshal of the English army; and after the taking of that town, in 1546, made captain-general of the king's forces in France. He was at this time knight of the garter. In the same year, attempting to intercept a convoy, he was defeated by the French, and soon after superseded in his command by the earl of Hertford.

Surry, after his return to England, conscious of his former services, and peevish under his disgrace, could not help reflecting on the king and council. This was his first step towards destruction. He had married Frances, the daughter of John earl of Oxford; and, after her death, is said to have made love to the princess Mary. For this the Seymours, rivals of the Norfolk family, and now in favour with the king, accused him of aspiring to the crown; adding, that he already presumed to quarter part of the royal arms with his own: but, whatever might be the pretence, the cause of his ruin was the jealousy and power of his enemies. In short, the destruction of the Howards being determined, Surry, and his father the duke of Norfolk, were committed to the Tower, in December 1546; and on the 13th of January following, Surry was tried at Guild-hall by a common jury, and beheaded on Tower-hill on the 19th day of the same month, nine days before the death of the king; who thus, that the measure of his crimes might be full, finished his life with the murder of his best subject. The accusations brought against this amiable and innocent young noble-

man on his trial, were so extremely ridiculous, that one is astonished how it was possible, even in the most despotic reign, to find a judge and jury so pusillanimously villanous as to carry on the farce of justice on the occasion. We boast of our excellent constitution, and our trial by juries; but this example may teach us, that our constitution and our juries are not incompatible with despotic monarchy. He was first interred in the church of All-hallows, Barkin, near Tower-hill; and afterwards, in the reign of king James I. removed to Farmingham in Suffolk, by his son Henry earl of Northampton.

As to the character of this unfortunate earl, all our poets have sung his praise. Mr Walpole begins his anecdotes of Surry with these words: "We now emerge from the twilight of learning to an almost classic author, that ornament of a boisterous, yet not unpolished court, the earl of Surry, celebrated by Drayton, Dryden, Fenton, Pope, illustrated by his own muse, and lamented for his unhappy death: a man (as Sir Walter Raleigh says) no less valiant than learned, and of excellent hopes." Leland calls him the conscript enrolled heir of Sir Thomas Wyatt, the elder, in his learning and other excellent qualities; and the author of *The Art of English Poetry* says, that the earl of Surry, and Sir Thomas Wyatt, may be justly called the *reformers of our poetry and style*. His poems were published in 1557, 12mo; and in 1565, 1574, 1585, 1587, 8vo. Several of the sonnets are by Sir Thomas Wyatt and others.

HOWARD (Charles), an able statesman and experienced seamen, was the son of lord William Howard, baron of Effingham, and born in 1536. He served under his father, who was lord high admiral of England, till the accession of queen Elizabeth. In January 1573, he succeeded his father in his title and estate: after which he successively became chamberlain of the household and knight of the garter; and in 1585 was made lord high admiral, at that critical juncture when the Spaniards were sending their ARMADA, in their opinion, to the assured conquest of this kingdom. When he received intelligence of the approach of the Spanish fleet, and saw the prodigious consequence it was to get out the few ships that were ready at Plymouth, he not only gave orders in every thing himself, but wrought also with his own hands, and the first night left the port with six ships. The next morning, though he had only 30 sail, and those the smallest of the fleet, he attacked the Spanish navy; but first dispatched his brother-in-law Sir Edward Hobby, to the queen to desire her to make the proper disposition of her land-forces for the security of the coast, and to hasten as many ships as possible to his assistance. His valour was conspicuously displayed in his repeated attacks of a superior enemy. The coolness of his temper was no less conspicuous; and it was owing to his magnanimity and prudence that the victory was so great. The queen expressed her sense of his merit in the most honourable terms; and granted him a pension for life. In 1596, he commanded in chief at sea, as Essex did by land, the forces sent against Spain, when his prudence and moderation were among the principal causes of the success the English met with in that great and glorious enterprize; so that, upon his return the next year, he was advanced to the dignity of earl of Nottingham.

Howard. The next eminent service in which his Lordship was engaged was in 1599, when the Spaniards seemed to meditate a new invasion. Her majesty, who always placed her safety in being too quick for her enemies, drew together, in a fortnight's time, such a fleet, and such an army, as took away all appearance of success from her foreign and domestic enemies; and she gave the earl the sole and supreme command of both the fleet and army, with the title of *lord lieutenant general of all England*, an office unknown in succeeding times. When age and infirmity had unfitted him for action, he resigned his office, and spent the remaining part of his life in ease and retirement, till the time of his decease, which happened in 1624, in the 87th year of his age.

HOWARD (John), Esq; a man of singular and transcendent humanity, was the son of a reputable tradesman in St Paul's church-yard. He was born about the year 1725 or 1726; and at a proper age was put apprentice to Mr Nathaniel Newnham, a wholesale grocer in Watling street. His father died, leaving only this son and a daughter, to both of whom he bequeathed handsome fortunes; and by his will directed that his son should not be considered of age till he was five and twenty. His constitution was thought very weak, and his health appeared to have been injured by the necessary duties of his apprenticeship; and therefore, at the expiration of it, he took an apartment in a lodging-house in Church-street, Stoke Newington, Middlesex; but not meeting with the tenderest treatment there, he removed to another lodging-house in the same street, which was kept by a widow lady Mrs Sarah Lardeau, a worthy sensible woman, but an invalid. Here he was nursed with so much care and attention, that he resolved to marry his landlady out of gratitude for her kindness. In vain she expostulated with him upon the extravagance of such a proceeding, he being about 28 and she about 51 years of age, and 20 years older in constitution: but nothing could alter his resolution, and they were privately married about the year 1752. She was possessed of a small fortune, which he presented to her sister. During his residence at Newington, the minister of the dissenting meeting-house there resigned his office, and a successor was elected; and Mr Howard, who was bred a dissenter, and stedfastly adhered all his life to that profession, proposed to purchase the lease of a house near the meeting-house, and to appropriate it as a parsonage-house for the use of the minister for the time being, and contributed 50*l.* for that purpose. His wife died November 10. 1755, aged 54; and he was a sincere and affectionate mourner for her death. About this time, it is believed, he was elected F. R. S. In the year 1756 he had the fortune to experience some of the evils which it afterwards became the business of his life to redress. He embarked that year in a Lisbon packet, the *Hanover*, in order to make the tour of Portugal; when the vessel was taken by a French privateer. "Before we reached Brest (says he*) I suffered the extremity of thirst, not having for above 40 hours one drop of water, nor hardly a morsel of food. In the castle at Brest I lay six nights upon straw; and observing how cruelly my countrymen were used there and at Morlaix, whither I was carried next, during the two months I was at Carhaix upon parole, I corresponded with the English prisoners at Brest, Morlaix, and Din-

nan: at the last of those towns were several of our ship's crew, and my servant. I had sufficient evidence of their being treated with such barbarity, that many hundreds had perished, and that 36 were buried in a hole at Dinnan in one day. When I came to England, still on parole, I made known to the commissioners of sick and wounded seamen the sundry particulars, which gained their attention and thanks. Remonstrance was made to the French court: our sailors had redress; and those that were in the three prisons mentioned above, were brought home in the first cartel ships.—Perhaps (adds Mr Howard) what I suffered on this occasion increased my sympathy with the unhappy people whose case is the subject of this book."

He afterwards, it is said, made the tour of Italy; and at his return settled at Brokenhurst, a retired and pleasant villa in the New Forest, near Lymington in Hampshire, having, April 25. 1758, married a daughter of Edward Leeds, Esq; of Croxton, Cambridgeshire, king's serjeant. This lady died in 1765 in child-bed, of her only child, a son, who unfortunately became lunatic. After her death Mr Howard left Lymington, and purchased an estate at Cardington, near Bedford.

"While he lived here in retirement (says Mr Palmer †), it was his meat and drink to make his neighbours happy. His neat but humble mansion was ever hospitable to a few select friends, but was never the scene of riot or luxurious banqueting. Though polite to all, he neither sought nor admitted the company of the profligate, however distinguished by rank or fortune.—His charity had no bounds, except those of prudence; and was not more commendable for the extent of it, than for the manner in which it was exercised. He gave not his bounty to countenance vice and idleness, but to encourage virtue and industry. He was singularly useful in furnishing employment for the labouring poor of both sexes, at those seasons when a scarcity of work rendered their situation most compassionate. And at other times, though never inattentive to the tale of woe, he was not easily imposed upon by it, but made himself acquainted with the case. He had indeed a general acquaintance with the cases and characters of the poor around him, and made it his business to visit the abodes of affliction. In circumstances of bodily disorder he often acted the part of a physician as well as a friend. But his kindness was not confined to the bodies of his fellow-creatures, it extended to their spiritual and immortal part. He carefully watched over the morals of his neighbourhood, and used his advice, his admonitions, and influence, to discountenance immorality of all kinds, and to promote the knowledge and practice of religion. As a most effectual means to this great end, he provided for the instruction of poor children, by erecting and supporting schools, which he carefully superintended. In short, he was a universal blessing to the village where he resided, in every part of which are to be seen the pleasing monuments of his munificence and taste.—His liberality extended also to adjacent places, in which there are many who will call him blessed. Nor was it confined to persons of his own religious persuasion, but comprehended the necessitous and deserving of all parties; while he was particularly useful in serving the interest of the Christian society to which

* On *Prisoners*, 4to, 1784, p. 11.

† *Funeral Sermons on the death of Mr Howard*.

Howard.

which he belonged. What wonder if such a man were universally beloved? Was it possible he should have an enemy? One however he had (and I never heard of more), an idle and dissolute wretch, who, having been often reprov'd by him for his vices, formed the desperate resolution to murder him as he was going to public worship, which he almost always did on foot. But Providence remarkably interposed to preserve so valuable a life, by inclining him that morning to go on horseback a different road."

But the sphere in which he had hitherto moved was too narrow for his enlarged mind. Being named in 1773 to the office of sheriff of Bedfordshire, from that time his scene of usefulness was extended. His office, as he himself observes, brought the distress of prisoners more immediately under his notice. A sense of duty induced him personally to visit the county-jail, where he observed such abuses, and such scenes of calamity, as he had before no conception of; and he soon exerted himself in order to a reform. With a view to obtain precedents for certain regulations which he purposed, he went to inspect the prisons in some neighbouring counties. But finding in them equal room for complaint and commiseration, he determined to visit the principal prisons in England. The farther he proceeded, the more shocking were the scenes presented to his view: which induced him to resolve upon exerting himself to the utmost, in order to a general reform in these horrid places of confinement; considering it as of the highest importance, not only to the wretched objects themselves, but to the community at large. Upon this subject he was examined in the house of commons in March 1774, when he had the honour of their thanks. This encouraged him to proceed in his design. He revisited all the prisons in the kingdom, together with the principal houses of correction. He also in 1775 enlarged his circuit by going into Wales, Scotland, and Ireland, where he found the same need of reformation.

One grand object which he had in view was, to put a stop to that shocking distemper called the *jail-fever*; which raged so dreadfully in many of the prisons, as to render them to the last degree offensive and dangerous: A distemper, by which more had been taken off than by the hands of the executioner; and which, in several instances, had been communicated from the prisoners into the courts of justice, and had proved fatal to the magistrates and judges, and to multitudes of persons who attended the trials, as well as to the families of discharged felons and debtors. Another end he proposed was, to procure the immediate release of prisoners, who, upon trial, were acquitted, but who often continued long to be unjustly detained for want of being able to pay the accustomed fees: As also to abolish many other absurd and cruel usages which had long prevailed. But the great object of all was, to introduce a thorough reform of morals into our prisons; where he had found the most flagrant vices to prevail in such a degree, that they were become seminaries of wickedness and villany, and the most formidable nuisances to the community; in consequence of the promiscuous intercourse of prisoners of both sexes, and of all ages and descriptions; whereby the young and less experienced were initiated, by old and hardened sinners, into all the

arts of villany and the mysteries of iniquity; so that, instead of being reformed by their confinement (which should be the chief end of punishment), those that were discharged became more injurious to society than before.

In order to the attainment of these great objects, Mr Howard spared no pains nor expence, and cheerfully exposed himself to much inconvenience and hazard; particularly from that malignant distemper, of which he saw many dying in the most loathsome dungeons, into which none, who were not obliged, besides himself, would venture. "I have been frequently (says Mr Howard) asked what precautions I use to preserve myself from infection in the prisons and hospitals which I visit. I here answer, next to the free goodness and mercy of the Author of my being, temperance and cleanliness are my preservatives. Trusting in divine Providence, and believing myself in the way of my duty, I visit the most noxious cells; and while thus employed, I fear no evil. I never enter an hospital or prison before breakfast; and in an offensive room, I seldom draw my breath deeply."

His laudable endeavours he had the pleasure to see, in some instances, crowned with success; particularly in regard to the healthiness of prisons, some of which were rebuilt under his inspection. Through his interposition also, better provision has been made for the instruction of prisoners, by the introduction of bibles and other pious books into their cells, and a more constant attendance of clergymen. The gaolers likewise have, by act of parliament, been rendered incapable of selling strong liquors, which had been the source of much drunkenness and disorder. But a minute detail of particulars is not to be expected here; for these the reader is referred to Mr Howard's publications, which show that much is yet wanting.

But in order to a more general and happy regulation, and the reformation of criminals, he determined to visit other countries, to see the plans there adopted; in hope of collecting some information which might be useful in his own country. For this purpose he travelled into France, Flanders, Holland, Germany, and Switzerland. Afterwards through the Prussian and Austrian dominions. He visited also the capitals of Denmark, Sweden, Russia, and Poland, and some cities in Portugal and Spain. In all these expensive and hazardous journeys, he denied himself the usual gratifications of travellers, and declined the honours which were offered him by persons of the first distinction, applying himself solely to his one grand object. To him the inspection of a jail, or hospital, was more grateful than all the entertainments of a palace. With what astonishment and gratitude he was received by their miserable inhabitants may easily be imagined, since while he made observations on their situation, he meditated their relief; and many distressed prisoners abroad, as well as at home, partook of his bounty, and some were liberated by it; for he considered all of every nation, and people, and tongue, as brethren. Nor was he sparing of advice, or of reproof, as he saw occasion, to persons of rank and influence, whereby the miseries of their countrymen might be relieved. As he courted the favour of none, neither did he fear the frowns of any; but, with a manly freedom and a Christian fortitude, spoke his mind to crowned heads (parti-

Howard.

Howard. (particularly the late emperor of Germany) in a manner to which they were not accustomed; which, however, in a person of such disinterested views, procured him reverence and esteem, and in some instances proved effectual for relieving the miserable and oppressed. On his return, he published in 1777, "The State of the Prisons in England and Wales, with Preliminary Observations, and an Account of some foreign Prisons." 4to. And in 1778 he took a third journey through the Prussian and Austrian dominions, and the free cities of Germany, and likewise extended his tour through Italy, and revisited some of the countries he had before seen. The observations he made in this tour were published in an appendix, 1780; containing also some remarks respecting the management of prisoners of war, and the hulks on the Thames. But wishing to acquire some further knowledge on the subject, he in 1781 again revisited Holland and some cities in Germany. He visited also the capitals of Denmark, Sweden, Russia, and Poland; and in 1783 some cities in Portugal and Spain, and returned through France, Flanders, and Holland. The substance of all these travels was afterwards thrown into one narrative, which was published in 1784. He also published a curious account of the Bastille, in 8vo; that infamous French prison happily now no more.

His travels and exertions, however, were not yet at an end. He conceived a further design, which was to visit the principal lazarettos in France and Italy, in order to obtain information concerning the best methods to prevent the spreading of the plague, with a view to apply them with respect to other infectious disorders. Not gaining all the satisfaction here which he wished for, he proceeded to Smyrna and Constantinople, where that most dreadful of human distempers actually prevailed, "pleasing himself (as he said) with the idea of not only learning, but of being able to communicate somewhat to the inhabitants of those distant regions." In the execution of this design, though he was so much exposed to danger, and actually caught the plague, "that merciful Providence (as he himself piously remarks) which had hitherto preserved him, was pleased to extend his protection to him in this journey also, and to bring him home once more in safety." In his return he revisited the chief prisons and hospitals in the countries through which he passed; and afterwards went again to Scotland, and then to Ireland, where he proposed a new and very important object; namely, to inspect the Protestant Charter Schools, in some of which he had before observed shameful abuses, which he had reported to a committee of the Irish House of Commons. In this more extensive tour, he took a particular account of what he observed amiss in the conduct of this noble charity, with a view to a reformation, and not without considerable success. In the course of these journeys, particular cities and communities were not unmindful to pay him proper respect. At Dublin, he was created by the university a Doctor of Laws; and the city of Glasgow and the town of Liverpool did honour to themselves by enrolling him among their members. Upon his return home, having again inspected the Prisons in England, and the hulks on the Thames, to see what alterations had been made for the better (which he found to be very considerable, though yet

imperfect), he published the result of his last laborious investigations, in "An Account of the principal Lazarettos in Europe, with various Papers relative to the Plague, together with further Observations on some Foreign Prisons and Hospitals, and additional Remarks on the present State of those in Great-Britain and Ireland," with a great number of curious plates. The work likewise contained Observations on Penitentiary Houses, which had been encouraged by act of parliament, for the correction and reformation of criminals, of which he and Dr Fothergill had been nominated by the king to be superintendants. Beside these, he published the Grand Duke of Tuscany's "new Code of Criminal Law with an English Translation:" and of all his publications he gave away a vast number of copies among his acquaintance in the most liberal manner. His laying open the horrors of despotism in a neighbouring country had very nearly exposed him to the sufferings of them; and had it not been for the timely notice of our ambassador, he had ended his days in the Bastille.

Not satisfied, however, with what he had already done, he concludes his "Account of Lazarettos" with announcing his "intention again to quit his country, for the purpose of revisiting Russia, Turkey, and some other countries, and extending his tour in the East. I am not insensible (says he) of the dangers that must attend such a journey. Trusting, however, in the protection of that kind Providence which has hitherto preserved me, I calmly and cheerfully commit myself to the disposal of unerring wisdom. Should it please God to cut off my life in the prosecution of this design, let not my conduct be uncandidly imputed to rashness or enthusiasm, but to a serious deliberate conviction that I am pursuing the path of duty, and to a sincere desire of being made an instrument of more extensive usefulness to my fellow-creatures than could be expected in the narrower circle of a retired life." Accordingly, to the great concern of his friends, he set out in summer 1789 on this hazardous enterprise; the principal object of which was to administer a medicine in high repute at home, in malignant fevers*, *Dr James's under a strong persuasion that it would be equally efficacious in the plague. In this second tour in the East "it did please God to cut off his life:" for, having spent some time at Cherson, a new settlement of the Empress of Russia, in the mouth of the Dnieper or Borysthenes, toward the northern extremity of the Black Sea, near Oczakow, he caught, in visiting the Russian hospital of that place, or as some say a young lady who was ill of the same complaint, a malignant fever, which carried him off on the 20th of January, after an illness of about twelve days: and after having been kept, according to his express directions to his servant, five days, he was buried, by his own desire, in the garden of a villa in the neighbourhood, belonging to a French gentleman from whom he had received great civilities, by his faithful servant who had attended him on his former journeyings, and whom he expressly enjoined not to return home till five weeks from his death. While absent on his first tour to Turkey, &c. his character for active benevolence had so much attracted the public attention, that a subscription was set on foot to erect a statue to his honour, and in no long space above L. 1500 was subscribed for that purpose.

purpose. But some of those who knew Mr Howard best, never concurred in the scheme, being well assured that he would neither countenance nor accede to it; and in consequence of two letters from Mr Howard himself† to the subscribers, the design was laid aside. It has, however, been resumed since his death: And surely, of all the statues or monuments ever erected by public gratitude to illustrious characters either in ancient or modern times, none was ever erected in honour of worth so genuine and admirable as his—who devoted his time, his strength, his fortune, and finally sacrificed his life, in the pursuits of humanity:—who (to adopt the expressive words of Mr Burke†) “visited all Europe [and the East], not to survey the sumptuousness of palaces, or the stateliness of temples; not to make accurate measurements of the remains of ancient grandeur, nor to form a scale of the curiosity of modern art; not to collect medals, or to collate manuscripts; but to dive into the depth of dungeons; to plunge into the infection of hospitals; to survey the mansions of sorrow and of pain; to take the gauge and dimensions of misery, depression, and contempt; to remember the forgotten; to attend to the neglected; to visit the forsaken; and to compare and collate the distresses of all men in all countries. His plan is original; and it is as full of genius as it is of humanity. It is a voyage of discovery, a circumnavigation of charity; and already the benefit of his labour is felt more or less in every country.”

HOWDEN, a town in the East Riding of Yorkshire, 180 miles from London, stands on the north side of the Ouse, has a market on Saturdays, and four fairs in the year. Here was formerly a collegiate church of five prebendaries, erected in the last century but one; adjacent to which the bishops of Durham, who possess many estates hereabouts with a temporal jurisdiction, have a palace. One of them built a very tall steeple to the church here, whither the inhabitants might retire in case of inundations; to which it is very liable from the great freshes that come down the Ouse sometimes at ebb. This part of the county is from hence called Howdenshire, and is watered by a conflux of several large rivers that fall into the Humber. At Howdendike is a ferry over the Ouse.

HOWE (John), a learned English nonconformist divine born in 1630. He became minister of Great Torrington in Devonshire, and was appointed household chaplain to Cromwell; but seems to have been free from the fanaticism then in fashion, as he offended Cromwell greatly by preaching against the notion of particular faith, which the ministers of his court were great advocates for. When Oliver died, he continued chaplain to Richard; and when Richard was deposed, he returned to Torrington, where he continued till the act of uniformity took place and set him aside. He afterwards settled at Utrecht, until the declaration for liberty of conscience was published by king James II. under shelter of which he returned to London, where he died in 1705. He published a great number of sermons and religious works, which have been reprinted together in two vols folio.

Howe's Island, a small island of the South Sea, discovered by captain Wallis, called by the inhabitants of the Society-Island *Mopeha*; lies in S. Lat. 16. 46. and W. Long. 154. 8.

Lord Howe's Island, a small island in the neighbourhood of New South Wales, discovered on February 17. 1788, S. Lat. 31. 36. E. Long. 159. 04. It is of an arched figure, lying from north-west to south-east, the two extremities including a space of about six miles, though, by reason of the curved figure of the island itself, it is near seven in length. It is deeply indented on the middle of the eastern part by a bay named Ross's Bay, and on the opposite and western part has another named Prince William Henry's Bay; so that the whole has the appearance of two islands joined together by an isthmus, which in some places is not above half a mile broad. On the southern part of that division which lies most to the northward are two considerable bays, named Callam's and Hunter's Bay; and on the south-western part of the other are two high mountains, the most southerly named Mount Gower, and the other Mount Lidgbird. The convex part of the island lying towards the north-east, and the concave side towards the opposite quarter, is terminated by two points named Point King and Point Philip. No fresh water was found on the island; but it abounds with cabbage-palms, mangrove, and manchineel trees, even up to the summits of the mountains. There are plenty of ganets, and a land fowl of a dusky brown colour, with a bill about four inches long, and feet like those of a chicken. These were found to be remarkably fine meat, and were very fat. There are many large pigeons, and the white birds found in Norfolk Island were also met with in this place. The bill of this bird is red, and very strong, thick, and sharp pointed. Great numbers of fine turtle frequent this island in summer, but go to the northward in winter. These, it was imagined, would prove of great service to the colony at Port Jackson; but, from some cause or other, it appears they have hitherto been disappointed. Plenty of fish were caught by a hook and line. At the distance of about four leagues from Lord Howe's Island is a very remarkable and high rock, to which the name of Ball's Pyramid has been given. This island may be approached without danger; but about four miles from the south-west part of the pyramid there is a very dangerous rock, which shows itself above the surface of the water, and appears not to be larger than a boat. The southern part of the island is lined with a sandy beach, which is guarded against the sea by a reef of coral rock, at the distance of half a mile from the beach, through which there are several small openings for boats; but there is nowhere a greater depth of water within the reef than four feet. By the account of Mr Watts, who visited this island in his return from Port Jackson, the isthmus which joins the two parts has evidently been overflowed, and the island disjoined, as in the very centre the men saw large beds of coral rocks and great quantities of shells; and on the east, which seems in general to be the weather-side, the sea has thrown up a bank of sand from 25 to 30 feet high, which serves as a barrier against future inundations. The island also appears to have suffered by volcanic eruptions, as great quantities of pumice-stones and other matters of that kind were found upon it. Mr Austin also found the whole reef which shelters the west bay a burnt-up mass. The time he visited the island was that of the incubation of the ganets, of which there were then prodigious

Howe.

Howel
Hoy.
ous numbers, their nests being only hollows made in the sand, there not being any quadrupeds on the island to disturb them. Besides the large pigeons already mentioned, they met with beautiful parrots and parroquets; a new species of the coote, as well as of the rail and magpie. They found likewise a very beautiful small bird of a brown colour with a yellow breast, and yellow on the wing, which seemed to be a species of humming bird. They found also a black bird like a sheerwater, having a hooked bill; and which burrows in the ground. The only insects met with here were the common earth worm and ants; which last were in great plenty. Besides the trees already mentioned, they found several esculent vegetables, as scurvy-grass, celery, spinach, endive, and samphire.

HOWEL (James), a voluminous writer of the 17th century, supported himself many years by writing and translating of books. Though he had been a zealous loyalist, he afterwards flattered Cromwell; yet on the restoration he was made historiographer to the king, being the first in England who enjoyed that title. He died in 1666.

HOWITZ, a kind of mortar, mounted upon a field-carriage like a gun. The difference between a mortar and a howitz is, that the trunnions of the first are at the end, and at the middle in the last. The invention of howitzes is of much later date than mortars, for they really had their origin from them. The constructions of howitzes are as various and uncertain as those of mortars, excepting the chambers, which are all cylindric. They are distinguished by the diameter of the bore; for instance, a ten inch howitz is that the diameter of which is 10 inches; and so of the smaller ones.

HOWTH, a promontory which forms the northern entrance of the bay of Dublin, having a small village about seven miles north-east from that city in the province of Leinster. It gives title of earl to the family of St Lawrence, who were so called from a victory obtained by them over the Irish on St Lawrence's day 1177, their former name being Tristram; and this place has continued in possession of the family above 600 years. N. Lat. 53. 21. W. Long. 6. 22. The shores off this hill are rocky and precipitous, affording, however, a few harbours for small craft. It was formerly called Ben-hedar, i. e. "the Birds promontory;" and celebrated for having Dun Criomthan, or the rath or royal palace of Criomthan erected on it, he having been chief or king of that district, and memorable for making several successful descents on the coast of Britain against the Romans in the time of Agricola. Howth, though now stripped of trees, was formerly covered with venerable oaks, and was a seat of the Druids; one of their altars still remains in a sequestered valley on the east side of the hill. The mansion-house is built in form of a castle, and was probably erected by Sir Armoricus Tristram. Near the house stands the family chapel, and on the western shore are the ruins of St Mary's church, with some ancient monuments of lord Howth's ancestors. Due west of Howth house are the ruins of St Fenton's church.

HOY, a small vessel, chiefly used in coasting, or carrying goods to or from a ship, in a road or bay, where the ordinary lighters cannot be managed with safety or convenience.

It would be very difficult to describe, precisely, the marks of distinction between this vessel and some others of the same size, which are also rigged in the same manner; because what is called a *boy* in one place, would assume the name of a *sloop* or *smack* in another; and even the people who navigate these vessels, have, upon examination, very vague ideas of the marks by which they are distinguished from those above mentioned. In Holland, the hoy has two masts; in England, it has but one, where the main-sail is sometimes extended by a boom, and sometimes without it. Upon the whole, it may be defined a small vessel, usually rigged as a sloop, and employed for carrying passengers and luggage from one place to another, particularly on the sea-coast.

Hoy, an island of Scotland, and one of the Orcades. It is about 10 miles long; and that part called *Waes* is fruitful and pretty populous, and is a good place for fishing.

HOYE, a town of Germany, in Westphalia, and capital of a county of the same name. It is seated on the river Weser, and is subject to the elector of Hanover. E. Long. 9. 0. N. Lat. 53. 5.

HUAHINE, one of the *SOCIETY-Islands*, in the South Sea, situated in S. Lat. 16. 43. W. Long. 150. 52. and is about seven or eight leagues in compass. Its surface is hilly and uneven, and it has a safe and convenient harbour. It was first discovered by captain Cook in 1769. It is divided by a deep inlet into two peninsulas connected by an isthmus, which is entirely overflowed at high water. From the appearance of its hills it may be concluded, that the country has at some period or other been the seat of a volcano. The summit of one of them had much the appearance of a crater, and a blackish spongy earth was seen upon one of its sides, which seemed to be lava; and the rocks and clay every where had a burnt appearance. The island is plentifully supplied with water by many rivulets which descend from the mountains and broken rocks. The inhabitants are nearly as fair as Europeans; and their conduct is bolder than that of the inhabitants of the other Society Islands. They are a stout large made people, some of the tallest being six feet three inches in height; they are extremely indolent, and seem to have as little curiosity as fear. The dogs are in great favour with all their women, "who could not have caressed them (says Mr Forster) with a more ridiculous affection if they had been European ladies of fashion." Here was seen a middle-aged woman, whose breasts were full of milk, offering them to a little puppy who had been trained up to suck them. The sight disgusted those who saw it so much, that they could not forbear expressing their dislike to it; but the woman smiled, and told them that she allowed young pigs to do the same. It appeared afterwards that this woman had lost her child. Some of the gentlemen were present at a dramatic entertainment on this island: the piece represented a girl running away from her parents; and seemed to be levelled at a female passenger who had come in captain Cook's ship from Otaheite, and who happened to be present at the representation. It made such an impression on the girl, that the gentlemen could scarce prevail upon her to see the piece out, or to refrain from tears while it was acting. It concluded with the reception she was supposed to meet with from her

Hoy.
Huahine.

Huber
Hudson.

her friends, which was made out not to be a very agreeable one.—These people introduce extempore pieces upon occasion; and it is most probable that this was meant as a satire upon the girl above mentioned, and to discourage others from acting in the same manner.

HUBER (Ulric), one of the greatest civilians in the 17th century, was born at Dockum in 1636. He became professor of law at Franeker; and wrote, 1. A treatise *De jure civitatis*. 2. *Jurisprudencia Frisica*. 3. *Specimen philosophiæ civilis*. 4. *Institutiones historiæ civilis*; and several other works which are esteemed. He died in 1694.

HUBERT (St), a town of the Netherlands, on the confines of Liege, with a very fine abbey, where they bring those that are bit by mad animals to be cured. E. Long. 5. 25. N. Lat. 34. 32.

HUBNER (John), a learned geographer of Germany, taught geography at Leipzig and Hamburg with extraordinary reputation; and died at Hamburg in 1732, aged 63. His principal work is A Geographical treatise, printed at Basil in 1746, in 6 vols 12mo.

HUDSON (Jeffrey). See DWARF.

HUDSON (Henry), an eminent English navigator, who, about the beginning of the last century, undertook to find out a passage by the north-east or north-west to Japan and China. For this purpose he was four times fitted out: he returned three times unsuccessful; but in the last voyage, in 1610, being persuaded that the great bay to which his name has been since given, must lead to the passage he sought, he wintered there, to prosecute his discovery in the spring. But their distresses during the winter producing a mutiny among his men, when the spring arrived, they turned him, with his son and seven sick men, adrift in his own shallop, and proceeded home with the ship. As Hudson and his unhappy companions were never heard of afterward, it is to be supposed they all perished.

HUDSON (John), a very learned English critic, born in 1662. He distinguished himself by several valuable editions of Greek and Latin authors; and, in 1701, was elected head keeper of the Bodleian library at Oxford. In 1712, he was appointed principal of St Mary's Hall, through the interest of the famous Dr Ratcliffe; and it is said that the university of Oxford is indebted for the most ample benefactions of that physician to Dr Hudson's solicitations. He died in 1719, while he was preparing for publication a catalogue of the Bodleian library, which he had caused to be fairly transcribed in six folio volumes.

Hudson's Bay, a large bay of North America, lying between 51 and 69 degrees of latitude, discovered in 1610 by Henry Hudson. This intrepid mariner, in searching after a north-west passage to the South-seas, discovered three straits, through which he hoped to find out a new way to Asia by America. He had made two voyages before on the same adventure; the first in 1607, and the second in 1608. In his third and last, 1610, he entered the straits that lead into this new Mediterranean, the bay known by his name; coasted a great part of it; and penetrated to eighty degrees and an half into the heart of the frozen zone. His ardour for the discovery not being abated by the difficulties he struggled with in this empire of winter, and
N° 158.

world of frost and snow, he staid here until the ensuing spring, and prepared in the beginning of 1611 to pursue his discoveries; but his crew, who suffered equal hardships, without the same spirit to support them, mutinied, seized upon him and seven of those who were most faithful to him, and committed them to the fury of the icy seas in an open boat. Hudson and his companions were either swallowed up by the waves, or gaining the inhospitable coast were destroyed by the savages; but the ship and the rest of the men returned home. Other attempts towards a discovery were made in 1612 and 1667; and a patent for planting the country, with a charter for a company, was obtained in the year 1670. In 1746 Captain Ellis wintered as far north as 57 degrees and a half, and Captain Christopher attempted farther discoveries in 1761. But besides these and the late voyages, which satisfy us that we must not look for a passage on this side of the latitude 67 degrees north, we are indebted to the Hudson's Bay Company for a journey by land; which throws much additional light on this matter, by affording what may be called demonstration, how much farther north, at least in some parts of their voyage, ships must go, before they can pass from one side of America to the other. The northern Indians, who come down to the company's factories to trade, had brought to the knowledge of our people a river, which on account of much copper being found near it, had obtained the name of the Copper-mine river. The company being desirous of examining into this matter with precision, directed Mr Hearne, a young gentleman in their service, and who having been brought up for the navy and served in it the war before last, was extremely well qualified for the purpose, to proceed over land under the convoy of those Indians, for that river, which he had orders to survey if possible quite down to its exit into the sea; to make observations for fixing the latitudes and longitudes; and to bring home maps and drawings both of it and the countries through which he should pass. Accordingly Mr Hearne set out from Prince of Wales's Fort, on Churchill river, latitude $58^{\circ} 47\frac{1}{2}'$ North, and longitude $94^{\circ} 7\frac{1}{2}'$ West from Greenwich, on the 7th of December 1770. On the 13th of June he reached the Copper-mine river, and found it all the way, even to its exit into the sea, encumbered with shoals and falls, and emptying itself into it over a dry flat of the shore, the tide being then out, which seemed by the edges of the ice to rise about 12 or 14 feet. This rise, on account of the falls, will carry it but a very small way within the river's mouth, so that the water in it had not the least brackish taste. Mr Hearne was nevertheless sure of the place it emptied itself into being the sea, or a branch of it, by the quantity of whale-bone and seal skins which the Esquimaux had at their tents; and also by the number of seals which he saw upon the ice. The sea at the river's mouth was full of islands and shoals as far as he could see by the assistance of a pocket telescope; and the ice was not yet (July 17th) broken up, but thawed away only for about three quarters of a mile from the shore, and for a little way round the islands and shoals which lay off the river's mouth. But he had the most extensive view of the sea when he was about eight miles up the river; from which station the extreme parts of it bore N. W.
by

Hudson.

Hudson's
Bay.Hudson's
Bay.

by W. and N. E. By the time Mr Hearne had finished his survey of the river, which was about one o'clock in the morning on the 18th, there came on a very thick fog and drizzling rain; and as he had found the river and sea in every respect unlikely to be of any utility, he thought it unnecessary to wait for fair weather to determine the latitude more exactly by observation; but by the extraordinary care he took in observing the courses and distances, walking from Congecathawhachaga, where he had two very good observations, he thinks the latitude may be depended on within 20' at the utmost. It appears from the map which Mr Hearne constructed of this singular journey, that the mouth of the Copper-mine river lies in latitude 72° N. and longitude 25° W. from Churchill river; that is about 119° W. of Greenwich. Mr Hearne's journey back from the Copper-mine river to Churchill lasted till June 30th 1772; so that he was absent almost a year and seven months. The unparalleled hardships he suffered, and the essential service he performed, met with a suitable reward from his masters, and he was made governor of Prince of Wales's Fort on Churchill river. But though the adventurers failed in the original purpose for which they navigated this bay, their project, even its failure, has been of great advantage to this country, as is shown under the article COMPANY (*Hudson's Bay.*)

The country lying round Hudson's Bay is called *New Britain*, or the country of the Esquimaux; comprehending *Labrador*, now North and South Wales. The entrance of the bay from the ocean, after leaving to the north Cape Farewell and Davis's Straits, is between Resolution isles on the north, and Button's isles on the Labrador coast to the south, forming the eastern extremity of the straits distinguished by the name of its great discoverer. The coasts are very high, rocky, and rugged at top; in some places precipitous, but sometimes exhibit large beaches. The isles of Salisbury, Nottingham, and Digges, are also very lofty and naked. The depth of water in the middle of the bay is a hundred and forty fathoms. From Cape Churchill to the south end of the bay are regular soundings; near the shore shallow, with muddy or sandy bottom. To the north of Churchill the soundings are irregular, the bottom rocky, and in some parts the rocks appear above the surface at low water. From Moose river or the bottom of the bay to Cape Churchill the land is flat, marshy, and wooded with pines, birch, larch, and willows. From Cape Churchill to Wager's Water the coasts are all high and rocky to the very sea, and woodless, except the mouths of Pockerekesko and Seal rivers. The hills on their back are naked, nor are there any trees for a great distance inland.

The mouths of all the rivers are filled with shoals; except that of Churchill, in which the largest ships may lie: but ten miles higher, the channel is obstructed with sand-banks; and all their rivers, as far as has been navigated, are full of rapids and cataracts from ten to sixty feet perpendicular. Down these rivers the Indian traders find a quick passage; but their return is a labour of many months. As far inland as the company have settlements, which is six hundred miles to the west, at a place called Hudson House, lat. 53. long. 106. 27 from London, is flat country: nor is it

VOL. VIII. Part II.

known how far to the eastward the great chain seen by our navigators from the Pacific Ocean branches off.

The climate even about Haye's river, in only lat. 57, is during winter excessively cold. The snows begin to fall in October, and continue falling by intervals the whole winter; and when the frost is most rigorous, in form of the finest sand. The ice on the rivers is eight feet thick. Port-wine freezes into a solid mass; brandy coagulates. The very breath fell on the blankets of the beds in the form of a hoar frost, and the bed-cloaths often were found frozen to the wall. The sun rises in the shortest day at five minutes past nine, and sets five minutes before three. In the longest day the sun rises at three, and sets about nine. The ice begins to disappear in May, and hot weather commences about the middle of June, which at times is so violent as to scorch the face of the hunters. Thunder is not frequent, but very violent. But there must be great difference of heat and cold in this vast extent, which reaches from lat. 50. 40, to lat. 63 north.—During winter the firmament is not without its beauties. Mock suns and halos are not unfrequent; they are very bright, and richly tinged with all the colours of the rainbow. The sun rises and sets with a large cone of yellowish light. The night is enlivened with the Aurora Borealis, which spreads a thousand different lights and colours over the whole concave of the sky, not to be defaced even by the splendour of the full moon; and the stars are of a fiery redness.

The eastern boundary of the bay is Terra di Labrador; the northern part has a straight coast facing the bay, guarded with a line of isles innumerable. A vast bay, called the Archiwinnipy Sea, lies within it, and opens into Hudson's Bay by means of Gulph Hazard, through which the Beluga whales dart in great numbers. Here the company had a settlement for the sake of the fishery, and for trading with the Esquimaux; but deserted it as unprofitable about the year 1758 or 1759. The eastern coast is barren past the efforts of cultivation. The surface is every where uneven, and covered with masses of stone of an amazing size. It is a country of fruitless valleys and frightful mountains, some of an astonishing height: the first watered by a chain of lakes, formed not from springs but rain and snow, so chilly as to be productive of only a few small trout. The mountains have here and there a blighted shrub, or a little moss. The valleys are full of crooked stunted trees, pines, fir, birch, and cedars, or rather a species of Juniper. In lat. 60, on this coast, vegetation ceases. The whole shore, like that on the west, is faced with islands at some distance from land. The inhabitants among the mountains are Indians; along the coasts Esquimaux. The dogs of the former are very small; of the latter large, and headed like a fox. Notwithstanding they have rein deer, they never train them for the sledge; but apply the dogs to that use. Walruses visit a place called Nuchvunk, in lat. 60, during winter; from thence the natives purchase the teeth with which they head their darts. Davis suspected that he had found a passage on this coast, in 1586, to the Western ocean; but it proves no more than a deep bay.

The laudable zeal of the Moravian clergy induced them to send, in the year 1752, missionaries from

Hudson's
Bay
Hudsonia.

Greenland to this country. They fixed on Nisbet's harbour for their settlement; but the first party was partly killed, partly driven away. In 1764, under the protection of our government, another attempt was made. The missionaries were well received by the Esquimaux, and the mission goes on with success.

The animals of these countries are, the moose deer, stags, rein-deer, bears, tygers, buffaloes, wolves, foxes, beavers, otters, lynxes, martins, squirrels, ermins, wild cats, and hares. The rein-deer pass in vast herds towards the north in October, seeking the extreme cold. The male polar bears rove out at sea, on the floating ice, most of the winter, and till June: the females lie concealed in the woods, or beneath the banks of rivers till March, when they come abroad with their twin cubs, and bend their course to the sea in search of their consorts. Several are killed in their passage; and those which are wounded show vast fury, roar hideously, and bite and throw up into the air even their own progeny. The females and the young, when not interrupted, continue their way to sea. In June the males return to shore, and by August are joined by their consorts, with the cubs, by that time of a considerable size. The feathered kinds are, geese, bustards, ducks, partridges, and all manner of wild-fowls. Indeed multitudes of birds retire to this remote country to Labrador and Newfoundland, from places most remotely south, perhaps from the Antilles; and some even of the most delicate little species. Most of them, with numbers of aquatic fowls, are seen returning southward with their young broods to more favourable climates. The savages in some respects regulate their months by the appearance of birds; and have their goose month from the vernal appearance of geese from the south. All the grouse kind, ravens, cinereous crows, titmouse, and Lapland finch, brave the severest winter; and several of the falcons and owls seek shelter in the woods. Of fish, there are whales, morse, seals, cod-fish, and a white fish preferable to herrings; and in their rivers and fresh waters, pike, perch, carp, and trout.

All the quadrupeds of these countries are clothed with a close, soft, warm fur. In summer there is here, as in other places, a variety in the colours of the several animals; when that season is over, which holds only for three months, they all assume the livery of winter, and every sort of beasts, and most of their fowls, are of the colour of the snow; every thing animate and inanimate is white. This is a surprising phenomenon. But what is yet more surprising, and what is indeed one of the most striking things, that draw the most inattentive to an admiration of the wisdom and goodness of Providence, is, that the dogs and cats from Britain that have been carried into Hudson's Bay, on the approach of winter have entirely changed their appearance, and acquired a much longer, softer, and thicker coat of hair than they had originally.

Hudson's Bay Company. See COMPANY.

Hudson's River, a large river of North America, which rises on the east of Lake Ontario, and running by Albany, and on the back of the south part of New-England through part of New-York, falls into the bay of the sea beyond the west end of Long-Island, and below the town of New-York.

HUDSONIA, in botany; a genus of the mono-

gynia order, belonging to the dodecandria class of plants. There is no corolla; the calyx is pentaphyllous and tubular: there are 15 stamina; the capsule is unilocular, trivalvular, and trispermous.

HUE and CRY, in law, the pursuit of a person who has committed felony on the high-way.—Of this custom, which is of British origin, the following deduction is given by Mr Whitaker. "When it was requisite for the Britons to call out their warriors into the field, they used a method that was particularly marked by its expeditiousness and decisiveness, and remains partially among us to this moment. They raised a cry, which was immediately caught up by others, and in an instant transmitted from mouth to mouth through all the region. And, as the notice passed along, the warriors snatched their arms, and hurried away to the rendezvous. We have a remarkable description of the fact in Cæsar, and there see the alarm propagated in 16 or 17 hours through 160 miles in a line. And the same practice has been retained by the Highlanders to our own time. When the lord of a clan received intelligence of an enemy's approach, he immediately killed a goat with his own sword, dipped the end of a half-burnt stick in the blood, and then gave it and the notice of the rendezvous to be carried to the next hamlet. The former symbolically threatened fire and sword to all his followers that did not instantly repair to the latter. The notice was dispatched from hamlet to hamlet with the utmost expedition. And in three or four hours the whole clan was in arms, and assembled at the place appointed. This was within these few years the ordinary mode by which the chieftains assembled their followers for war. The first person that received the notice, set out with it at full speed, delivered it to the next that he met, who instantly set out on the same speed, and handed it to a third. And, in the late rebellion of 1745, it was sent by an unknown hand through the region of Breadalbane; and, flying as expeditiously as the Gallick signal in Cæsar, traversed a tract of 32 miles in three hours. This quick method of giving a diffusive alarm is even preserved among ourselves to the present day; but is applied, as it seems from Cæsar's account above to have been equally applied among the Celtæ, to the better purposes of civil polity. The *butesium* and *clamour* of our laws, and the *hue and cry* of our own times, is a well-known and powerful process for spreading the notice and continuing the pursuit of any fugitive felons. The cry, like the clamour of the Gauls or the summons of the Highlanders, is taken from town to town and from county to county; and a chain of communication is speedily carried from one end of the kingdom to the other."

HUER, a name given to certain fountains in ICELAND, of a most extraordinary nature; forming at times *jets d'eau* of scalding water ninety-four feet high and thirty in diameter, creating the most magnificent gerbes that can be imagined, especially when backed by the setting sun. They arise out of cylindrical tubes of unknown depths: near the surface they expand into apertures of a funnel shape, and the mouths spread into large extent of stalactitical matter, formed of successive scaly concentric undulations. The playing of these stupendous spouts is foretold by noises roaring like the cataract of Niagara. The cylinder

Plate
CCXXXVI.

der begins to fill: it rises gradually to the surface, and gradually encreases its height, smoking amazingly, and flinging up great stones. After attaining its greatest height it gradually sinks till it totally disappears. Boiling *jets d'eaux* and boiling springs are frequent in most parts of the island. In many parts they are applied to the culinary uses of the natives. The most capital is that which is called *Geyser* or *Geyfer*, in a plain rising into small hills, and in the midst of an amphitheatre, bounded by the most magnificent and various-shaped icy mountains; among which the three-headed Hecla soars pre-eminent. See ICELAND, N° 4.—These huers are not confined to the land; they rise in the very sea, and form scalding fountains amidst the waves. Their distance from the land is unknown; but the new volcanic isle, twelve miles off the point of Reickenes, emitting fire and smoke, proves that the subterraneous fires and waters extend to that space; for those awful effects arise from the united fury of these two elements.

HUESCA, an ancient and considerable town of Spain, in the kingdom of Arragon, with a bishop's see and an university. It is seated on the Issuela, in a soil producing excellent wine, in W. Long. o. 13. N. Lat. 40. 2.

HUESCAR, or GUESCAR, a town of Spain, in the kingdom of Granada, seated on a plain in W. Long. 1. 45. N. Lat. 37. 32.

HUESNE, or HUENA, a small island in the Baltic Sea, in the Sound, where was the famous observatory of Tycho Brahe. E. Long. 13. 5. N. Lat. 55. 54.

HUET (Peter Daniel), a very learned French writer, born at Caen in Normandy, on the 8th of February 1630. He discovered, from his infancy, a great inclination to the study of polite literature and the sciences, and at first applied himself to the law; but Des Cartes's principles, and Bochart's sacred geography, made him change his studies for those of philosophy, mathematics, the languages, and antiquities. His admiration for Bochart made him desirous of knowing him. He contracted a very strict friendship with him, and accompanied that learned man to Sweden. Here Christina would have engaged him in her service; but he, sensible of her inconstant temper, returned to France. All he brought with him was a copy of a MS. of Origen, which he transcribed at Stockholm. He refused several offers from Christina after she abdicated and went to Rome, and from Gustavus her successor. In 1670, Mr Bossuet being appointed by the king preceptor to the dauphin, his majesty chose Mr Huet for his colleague, with the title of *sub preceptor to the prince*. It was he that formed the plan of the commentaries in *usum Delphini*, and directed the execution. His sentiments of piety determined him to enter into holy orders, which he did at the age of 46. Soon after this, he was presented by the king to the abbey of Aunay; and in 1685 was nominated to the bishopric of Soissons, which he exchanged for the see of Avranches. After governing that diocese ten years, he resigned, and was made abbot of Fontenay near Caen. His love to his native place determined him to fix there. But lawsuits coming upon him, he retired to Paris, and lodged among the Jesuits in the *Maison Professe*, whom he

had made heirs to his library. A severe distemper weakened his body extremely, but not the vivacity of his genius: he wrote his own life in a very elegant style; and died in 1721, aged 91. He was a man of very agreeable conversation; and of great probity, as well as immense erudition.—The following are the titles of his principal works. 1. *De claris interpretibus, et de optimo genere interpretandi*. 2. An edition of Origen's commentaries on the holy Scriptures, in Greek and Latin. 3. A treatise on the origin of the Romans. 4. *Demonstratio evangelica*, folio. 5. *Quæstiones Alnetane de concordia rationis et fidei*. 6. Of the situation of the terrestrial paradise, in French. 7. A history of the commerce and navigation of the ancients, which has been translated into English. 8. *Commentarius de rebus ad eum pertinentibus*. 9. *Huetiana*. 10. Latin and Greek verses, &c.

HUGHES (John), an ingenious and polite writer, was born in 1677. In the earliest parts of his youth, he cultivated the sister-arts, poetry, drawing, and music, in each of which he by turns made a considerable progress; but followed those and his other studies only as agreeable amusements, under frequent confinement on account of his ill state of health. The lord Chancellor Cowper made him secretary for the commissions of the peace without his knowledge, and distinguished him with singular marks of his esteem. He continued in the same employment under the earl of Macclesfield, and held it to the day of his death; which happened in 1719, the very night in which his tragedy, intitled *The siege of Damascus*, was first acted. He was then 42. He translated Fontenelle's dialogues of the dead, Vertot's revolutions of Portugal, and the letters of Abelard and Eloisa. He gave a very accurate edition of Spencer's works, with his life, a glossary, and remarks; and wrote several papers in the Tatler, Spectator, and Guardian. Mr Duncombe, who married his sister, collected his poems and essays in 2 vols 12mo, in 1735.

HUGHLY, a town of Asia, in the kingdom of Bengal, seated on the most westerly branch of the river Ganges. It is of large extent, reaching about two miles along the river-side, and drives a great trade in all the commodities of that country; affording rich cargoes for 50 or 60 ships annually, besides what is brought on carriages to the neighbouring towns. Saltpetre is brought hither from Patna in vessels above 50 yards long and five broad. The inhabitants are chiefly Indians; but there are also Portuguese, English, and other Europeans. E. Long. 87. 55. N. Lat. 22. o.

HUGO CAPET, chief of the third race of the kings of France, being count of Paris and Orleans: he was raised to the throne for his military valour and public virtues in 987. See FRANCE, n° 38.

HUGONIA, in botany: A genus of the decandria order, belonging to the monadelphia class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is pentapetalous; the fruit is a plum with a striated kernel.

HUGUENOTS, an appellation given by way of contempt to the reformed or Protestant Calvinists of France.

The name had its first rise in 1560; but authors are

Hughes
||
Huguenots.

Huguenots, not agreed as to the origin and occasion thereof: but one of the two following seems to be the least forced derivation.

One of the gates of the city of Tours is called the gate *Fourgon*, by corruption from *feu Hugon*, i. e. the late Hugon. This Hugon was once count of Tours, according to Eginhardus, in his life of Charles the Great, and to some other historians. He was it seems a very wicked man, who by his fierce and cruel temper made himself dreadful; so that after his death he was supposed to walk about in the night-time, beating all those he met with: this tradition the judicious Thuanus has not scrupled to mention in his history. Davila and other historians pretend, that the nickname of *Huguenots* was first given to the French Protestants, because they used to meet in the night-time in subterraneous vaults near this gate of Hugon; and what seems to countenance this opinion is, that they were first called by the name of *Huguenots* at this city of Tours.

Others assign a more illustrious origin to that name; and say that the leaguers gave it to the reformed, because they were for keeping the crown upon the head of the present line descended from Hugh Capet; whereas they were for giving it to the house of Guise, as descended from Charles the Great.

Others again derive it from a French and faulty pronunciation of the German word *eidgenossen*, signifying confederates, and originally applied to that valiant part of the city of Geneva, which entered into an alliance with the Swiss cantons, in order to maintain their liberties against the tyrannical attempts of Charles III. duke of Savoy.

These confederates were called *Eignots*, whence *Huguenots*.

The persecution which they underwent has scarce its parallel in the history of religion: though they obtained a peace from Henry III. in 1576, it was only of short continuance; and their sufferings, mitigated by the famous edict of Nantes, granted to them in 1598 by Henry IV. were again renewed, after the revocation of this edict, by Louis XIV. in 1685.

HULK, an old ship of war, fitted with an apparatus, to fix or take out the masts of his majesty's ships, as occasion requires.

The mast of this vessel is extremely high, and withal properly strengthened by *sbrouds* and *slays*, in order to secure what are called the *sheers*, which serve, as the arm of a crane, to hoist out or in the masts of any ship lying alongside. The sheers are composed of several long masts, whose heels rest upon the side of the hulk, and having their heads declining outward from the perpendicular, so as to hang over the vessel whose masts are to be fixed or displaced. The tackles, which extend from the head of the mast to the sheer-heads, are intended to pull in the latter towards the mast-head, particularly when they are charged with the weight of a mast after it is raised out of any ship, which is performed by strong tackles depending from the sheer-heads. The effort of these tackles is produced by two capsterns, fixed on the deck for this purpose.

HULK, is also a name bestowed on any old vessel laid by as unfit for further service. It is probably de-

rived from the *ολλυδαε*, or vessels of burthen, of the ancient Grecians.

HULL, in the sea-language, is the main body of a ship, without either masts, yards, sails, or rigging. Thus *to strike a Hull* in a storm, is to take in her sails, and to lash the helm on the lee-side of the ship; and *to hull*, or *lie a-hull*, is said of a ship whose sails are thus taken in, and helm lashed a-lee.

HULL, a river in Yorkshire, which falls into the Humber at *Kingston upon Hull*. See **KINGSTON**.

HUMAN, in general, is an appellation given to whatever relates to mankind: thus we say, the human soul, human body, human laws, &c.

HUMANITY, the peculiar nature of man, whereby he is distinguished from all other beings.

HUMANITIES, in the plural, signify grammar, rhetoric, and poetry, known by the name of *literæ humaniores*; for teaching of which, there are professors in the universities of Scotland, called *humanists*.

HUMBER, a river formed by the Trent, Ouse, Derwent, and several other streams. By the late inland navigation, it has a communication with the rivers Mersey, Dee, Ribble, Severn, Thames, Avon, &c. which navigation, including its windings, extends above 500 miles, in the counties of Lincoln, Nottingham, York, Lancaster, Westmoreland, Chester, Stafford, Warwick, Leicester, Oxford, Worcester. It divides Yorkshire from Lincolnshire, and falls into the German ocean near Holderness.

HUME (David, Esq;) a late celebrated philosopher and historian, was born in the south part of Scotland on the 26th of April O. S. in the year 1711. Being the younger son of a country gentleman of good family, but no great fortune, his patrimony was of consequence insufficient to support him. For this reason he was declined for the bar, and passed through his academical courses in the university of Edinburgh; but being more inclined to studies of a different nature, he never put on the gown, nor even took the introductory steps necessary for that purpose. The writings of Locke and Berkeley had directed the attention of the generality of learned men towards metaphysics; and Mr Hume having early applied himself to studies of this kind, published in 1739 the two first volumes of his *Treatise of human nature*, and the third the following year. He had the mortification, however, to find his book generally decried; and to perceive, that the taste for systematic writing was now on the decline. He therefore divided this treatise into separate Essays and Dissertations, which he afterwards published at different times with alterations and improvements.

In 1742, Mr Hume published two small volumes, consisting of Essays moral, political, and literary. These were better received than his former publication; but contributed little to his reputation as an author, and still less to his profit; and his small patrimony being now almost spent, he accepted an invitation from the marquis of Annandale to come and live with him in England. With this nobleman he staid a twelve-month; during which time his small fortune was considerably increased. He then received an invitation from General St Clair, to attend him as a secretary to his expedition, which was at first meant against Cana-

Hull

Hippopotamus.

A. Bell Pin. W. Al. Sculptor fecit.

Hume. da, but afterwards ended in an excursion against the coast of France. In 1747, he received an invitation from the general to attend him in the same station in his military embassy to the courts of Vienna and Turin. He then wore the uniform of an officer; and was introduced at these courts as aid de-camp to the general, along with Sir Harry Erskine and captain Grant, afterwards general Grant. In 1749, he returned to Scotland, and lived two years with his brother at his country-house; where he composed the second part of his essays, called *Political Discourses*. And now the general approbation of his performances was indicated by a more extensive sale than formerly, and likewise by the numerous answers published by different persons in order to counteract their supposed pernicious tendency. In 1752, were published at Edinburgh his *Political Discourses*, the only work of his which was well received on its first appearance; and the same year, at London, his *Inquiry concerning the Principles of Morals*, which in his own opinion was incomparably the best of all his performances. This year also he was appointed librarian to the faculty of Advocates at Edinburgh; the principal advantage resulting from which employment was, that he had by that means the command of a large library. He then formed the plan of writing the History of England: but deeming the whole to be too extensive, he confined his history to that of Britain under the house of Stuart. The book was almost universally decried on its first appearance, and soon after seemed to sink in oblivion. Dr Herring primate of England, and Dr Stone primate of Ireland, were the only literati of the author's acquaintance who approved of the work, and sent him messages not to be discouraged.

Notwithstanding the approbation of these eminent men, however, Mr Hume's spirits were so much sunk by his bad success, that he had some thoughts of retiring to France, changing his name, and bidding adieu to his own country for ever; but his design was rendered impracticable by the breaking out of the war of 1755 between France and Britain. He then published his *Natural History of Religion*; to which an answer was published, soon after its appearance, in the name of Dr Hurd bishop of Litchfield and Coventry; of which, however, he hath since disclaimed being the sole author. In 1756, the second volume of the History of the Stuarts was published, two years after the appearance of the first. This was better received, and helped to retrieve the character of the former volume. Three years after, his History of the House of Tudor made its appearance; which was almost as ill received as the History of the Stuarts had been, the reign of Elizabeth being particularly obnoxious. The author, however, had now learned to despise popular clamours; and continued to finish at his leisure the more early part of the English history, which was published in 1761, and was received with tolerable success.

Mr Hume being now turned of fifty, and having obtained by the sale of his books a competent and independent fortune, retired into his native country of Scotland, determined never more to set his foot out of it. From this resolution, however, he was diverted by the earl of Hertford; whom he attended as secretary on his embassy to Paris in 1763. In 1765, the

earl being appointed lord lieutenant of Ireland, Mr Hume was intrusted with the sole management of the business of the state till the arrival of the duke of Richmond towards the latter end of the year. In 1767, he returned to Edinburgh, with a much larger income, procured to him by the earl of Hertford, than he formerly had; and now formed the same design he had formerly entertained, namely, of burying himself in his philosophical retreat. In this, however, he was again disappointed, by receiving an invitation from general Conway to be under secretary; and this invitation he was prevented from declining, both by the character of the person, and his connections with lord Hertford. In 1769 he returned to Edinburgh, possessed of L. 1000 a-year, healthy, and though somewhat stricken in years, yet having a prospect of long enjoying his ease, and of seeing the increase of his reputation. Of his last illness and character, he himself gives the following account. "In spring 1775, I was struck with a disorder in my bowels; which at first gave me no alarm, but has since, as I apprehend it, become mortal and incurable. I now reckon upon a speedy dissolution. I have suffered very little pain from my disorder; and what is more strange, have, notwithstanding the great decline of my person, never suffered a moment's abatement of my spirits; inso-much, that were I to name the period of my life which I should most choose to pass over again, I might be tempted to point to this latter period. I possess the same ardour as ever in study, and the same gaiety in company. I consider, besides, that a man of sixty-five, by dying, cuts off only a few years of infirmities; and though I see many symptoms of my literary reputation breaking out at last with additional lustre, I knew that I could have but few years to enjoy it. It is difficult to be more detached from life than I am at present.

"To conclude, historically, with my own character, I am, or rather was (for that is the style I must now use in speaking of myself, which emboldens me the more to speak my sentiments); I was, I say, a man of mild dispositions, of command of temper, of an open, social, and cheerful humour, capable of attachment, but little susceptible of enmity, and of great moderation in all my passions. Even my love of literary fame, my ruling passion, never soured my temper, notwithstanding my frequent disappointments. My company was not unacceptable to the young and careless, as well as to the studious and literary; and as I took a particular pleasure in the company of modest women, I had no reason to be displeased with the reception I met with from them. In a word, though most men any wise eminent have found reason to complain of calumny, I never was touched, or even attacked, by her baleful tooth: and though I wantonly exposed myself to the rage of both civil and religious factions, they seemed to be disarmed in my behalf of their wonted fury. My friends never had occasion to vindicate any one circumstance of my character and conduct: not but that the zealots, we may well suppose, would have been glad to invent and propagate any story to my disadvantage, but they could never find any which they thought would wear the face of probability. I cannot say there is no vanity in making this funeral oration of myself, but I hope it is not a misplaced

Humecta-
tion
||
Humour.

misplaced one; and this is a matter of fact which is easily cleared and ascertained."

His fears concerning the incurableness of his disorder proved too true. He died on the 25th of August 1776; and was interred in the Calton burying-ground, Edinburgh, where a monument is erected to his memory.

HUMECTATION, formed of humour, moisture, moistening, in pharmacy, the preparing of a medicine, by steeping it a while in water, in order to soften and moisten it when too dry; or to cleanse it, or prevent its subtle parts from being dissipated in grinding, or the like.

HUMECTATION is also used for the application of moistening remedies.

In this sense we say, embrocations, emplasters, unctions, humectations, fomentations, &c.

HUMERUS, or *Os HUMERI*, in anatomy, the uppermost bone of the arm, popularly called the *shoulder-bone*; extending from the scapula, or shoulder-blade, to the upper end of the cubitus, or elbow. See **ANATOMY**, n° 47.

HUMIDITY, that quality in bodies whereby they are capable of wetting other bodies. This differs very much from fluidity; and seems to be merely a relative thing, depending on the congruity of the component particles of the liquor to the pores of such particular bodies as it is capable of adhering to, penetrating a little into, or wetting. Thus, for instance, quicksilver is not a moist thing with regard to our hands or clothes; but may be called so in reference to gold, tin, or lead, to whose surfaces it will perfectly adhere, and render them soft and moist.

HUMILIATI, a congregation of religious in the church of Rome, established by some Milanese gentlemen on their release from prison, where they had been confined under the emperor Conrad, or, as others say, under Frederick I. in the year 1162. This order, which acquired great wealth, and had no less than 90 monasteries, was abolished by pope Pius V. in 1570, and their houses given to the Dominicans and Cordeliers for their luxury and cruelty.

HUMILIATION, the act of humbling, i. e. of abating a person's pride, and bringing him lower in his opinion.

In this sense, humiliation stands distinguished from mortification: humiliation brings down the mind; mortification subdues the flesh.

HUMILITY, in ethics, is a virtue consisting in the moderate value which a person puts upon himself, and every thing relating to him. Or, more particularly, it consists in not attributing to ourselves any excellence or good which we have not; in not over-rating any thing which we have or do; in not taking an immoderate delight in one's self; in not assuming more of the praise of a quality or action than belongs to us; and in a lowly sense and acknowledgment of our imperfections, errors, and sins. This virtue expresses itself in the modesty of our appearance, of our pursuits, and of our behaviour towards other men. It is distinguished from affectation, bashfulness, and meanness.

HUMMING-BIRD. See **TROCHILUS**.

HUMOUR, from the Latin *humor*, in its original signification, stands for moisture in general; from whence it has been restrained to signify the moisture of

animal bodies, or those fluids which circulate through them. Humour, Humphrey.

It is distinguished from moisture in general in this, that humours properly express the fluids of the body; when, in a vitiated state, it would not be improper to say, that the fluids of such a person's body were full of humours.

The only fluids of the body, which, in their natural and healthful state, are called *humours*, are those in the eye; we talk of the aqueous humour, the crystalline humour, without meaning any thing that is morbid or diseased: yet, when we say in general, that such a person has got a humour in his eye, we understand it in the usual sense of a vitiated fluid.

As the temper of the mind is supposed to depend upon the state of the fluids in the body, **HUMOUR** has come to be synonymous with temper and disposition. A person's humour, however, is different from his *disposition*, in this, that humour seems to be the disease of a disposition: it would be proper to say that persons of a serious temper or disposition of mind, were subject to melancholy humours; that those of a delicate and tender disposition, were subject to peevish humours.

Humour may be agreeable or disagreeable: but it is still humour; something that is whimsical, capricious, and not to be depended upon. An ill-natured man may have fits of good-humour, which seem to come upon him accidentally, without any regard to the common moral causes of happiness or misery.

A fit of cheerfulness constitutes the whole of good-humour; and a man who has many such fits, is a good-humoured-man: yet he may not be good-natured; which is a character that supposes something more constant, equable, and uniform, than what was requisite to constitute good humour.

HUMOUR is often made use of to express the quality of the imagination, which bears a considerable resemblance to wit.

Wit expresses something that is more designed, concerted, regular, and artificial; humour, something that is more wild, loose, extravagant, and fantastical; something which comes upon a man by fits, which he can neither command nor restrain, and which is not perfectly consistent with true politeness. Humour, it has been said, is often more diverting than wit; yet a man of wit is as much above a man of humour, as a gentleman is above a buffoon; a buffoon, however, will often divert more than a gentleman. The duke of Buckingham, however, makes humour to be all in all: wit, according to him, should never be used, but to add an agreeableness to some proper and just sentiment, which, without some such turn, might pass without its effect. See **WIT**.

HUMPHREY (Dr Lawrence), a very learned English divine in the 16th century, who, during the persecution under queen Mary, retired with other Protestant refugees to Zurich. He returned on the accession of queen Elizabeth; and was made president of Magdalene college, Oxford, dean of Gloucester, and then dean of Winchester. He was a great and general scholar, an able linguist, and a deep divine; and published, 1. *De religionis conservatione et reformatione, deque primatu regum.* 2. *De ratione interpretandi auctores.* 3. *Optimates; sive de nobilitate, ejusque origine.* 4. Sermons, and other works. He died in 1590.

HUMULUS,

Humulus,
Hundred.

HUMULUS, the **HOP**: A genus of the pentandria order, belonging to the diœcia class of plants; and in the natural method ranking under the 53d order, *Scabridæ*. The male calyx is pentaphyllous; there is no corolla; the female calyx is monophyllous, patent obliquely, and entire, there is no corolla; but two styles; and one seed within the calyx, the latter consisting of one large leaf. There is only one species, viz. the lupulus, which is sometimes found wild in hedges near houses and gardens, but probably is not indigenous. The stalk is weak and climbing; it creeps up the support in a spiral, ascending always from the right hand to the left. The stalk and the leaves are rough to the touch; the upper leaves are heart-shaped, the lower ones divided into three lobes serrated on the edges, and grow in pairs on long footstalks. The male flowers grow on a distinct plant on branched peduncles; the females on peduncles in pairs of the form of a *strobilus* or cone, composed of large imbricated calyces containing each one or two seeds. For the culture and uses of hops, see the articles **HOP** and **HUSBANDRY**.

HUNDRED, **HUNDREDUM**, or *Centuria*, a part or division of a county; which was anciently so called from its containing an hundred families, or from its furnishing an hundred able men for the king's wars. After king Alfred's dividing this kingdom into counties, and giving the government of each county to a sheriff, these counties were divided into hundreds, of which the constable was the chief officer. The grants of hundreds were at first made by the king to particular persons: but they are not now held by grant or prescription, their jurisdiction being devolved to the county-court; a few of them only excepted, that have been by privilege annexed to the crown, or granted to some great subjects, and still remain in the nature of a franchise.

HUNDRED-Court. This is only a larger *Court Baron*, being held for all the inhabitants of a particular hundred instead of a manor. The free suitors are here also the judges, and the steward the register, as in the case of a court-baron. It is likewise no court of record; resembling the former in all points, except that in point of territory it is of a greater jurisdiction. This is said by Sir Edward Coke to have been derived out of the county-court for the ease of the people, that they might have justice done them at their own doors, without any charge or loss of time: but its institution was probably co-eval with that of hundreds themselves, which were formerly observed to have been introduced though not invented by ALFRED, being derived from the policy of the ancient Germans. The *centeni*, we may remember, were the principal inhabitants of a district composed of different villages, originally in number an *hundred*, but afterwards only called by that name; and who probably gave the same denomination to the district out of which they were chosen. Cæsar speaks positively of the judicial power exercised in *their* hundred-courts and courts-baron. "*Principes regionum, atque pagorum*," (which we may fairly construe, the lords of hundreds and manors) "*inter suas jus dicunt, controversiasque minuunt*." And Tacitus, who had examined their constitution still more attentively, informs us not only of the authority of the lords, but that of the *centeni*, the hundredors, or jury; who were taken out of the common freehold-

ers, and had themselves a share in the determination. "*Eliguntur in conciliis et principes, qui jura per pagos vicisque reddunt: centeni singulis, ex plebe comites, consilium simul et auctoritas, adfunt*." This hundred-court was denominated *hæreda* in the Gothic constitution. But this court, as causes are equally liable to removal from hence as from the common court-baron, and by the same writs, and may also be reviewed by writ of false judgment, is therefore fallen into equal disuse with regard to the trial of actions.

HUNGARY, a kingdom of Europe, the greatest part of which was anciently called *Pannonia*. It had the name of *Hungary* from the Hunns, a Scythian or Tartar nation, who subdued it in the ninth century. It lies between the 18th and 22d degrees of east long. and betwixt the 45th and 49th degrees of north lat. being bounded to the north by the Carpathian mountains, which separate it from Poland; to the south by Servia, and the river Drave, which separates it from Sclavonia; to the west by Moravia, Austria, and Stiria; and to the east by Walachia and Transylvania. It is about 240 miles in length, and 235 in breadth; and is divided into the Upper and Lower Hungary, the former being that part which lies towards the east, and the latter that which lies towards the west.

The northern parts of the kingdom are mountainous and barren, but healthy; the southern, on the contrary, are level, and exceeding fruitful, but not very healthy. The country along the Danube, from Presburg to Belgrade, for upwards of 200 miles, is one continued plain, and no soil can be more fertile; but the air, by reason of the many swamps and morasses, is not so wholesome as on the higher and drier grounds. Here are mines of gold, silver, copper, iron, lead, quicksilver, cinnabar, antimony, yellow orpiment, sulphur, vitriol, marcasite, salt native and factitious, saltpetre, magnets, asbestos or stone-flax, marble of several colours, alabaster, with diamonds, and all sorts of precious stones. Corn is in such plenty, that it is sold for one sixth of its price in England. Their grapes are large and luscious; and their wines preferred to any in Europe. They have vast numbers of cattle and horses, the latter mostly mouse-coloured, with buffaloes, deer, wild-fowl, game, and fish, and many species of wild beasts, particularly chamois, goats, bears, and lynxes. Of vegetables, besides vines, and the common sorts, here are tobacco, saffron, buck-wheat, millet, melons, and chefnuts. Here also are excellent warm baths, and springs of various kinds and qualities. The chief mountains of Hungary are the Crapack or Carpathian, which is the general name for all those that separate this kingdom from Poland, Moravia, Silesia, and some part of Austria. The sides of most of them are covered with wood, and their tops with snow. The chief rivers are the Danube, the Drave, the Save, the Wag or Waag, the Gran, the Temes, the Raab, and Theiss, all well stocked with fish. There are several lakes among the Carpathian mountains, and some also in the lowlands.

The inhabitants are a mixture of the descendants of the ancient Huns, Sclavonians, Camani, Germans, Walachians, Greeks, Jews, Turks, and a wandering people called *Zigduns*, said to be of uncertain origin, but.

Hungary.

Hungary. but probably the same as those we called *gyppies*. The Hungarians are said to be of a sanguine choleric temper, and somewhat fierce, cruel, proud, and revengeful. They have been always reputed good soldiers, being much more inclined to arms, martial exercises, and hunting, than to arts, learning, trade, or agriculture. The nobility affect great pomp and magnificence, and are much addicted to feasting and carousing. The men in general are strong and well proportioned. They shave their beards, but leave whiskers on the upper-lip; wearing fur caps on their heads, a close-bodied coat girt with a sash, with a short cloak or mantle over all, so contrived as to be buckled under the arm, and leave the right hand at liberty. Their horse are called *buffars*, and their foot *heydukes*. The former wear a broad-sword, or scymeter, and carry a hatchet or battle-ax. Their horses are fleet, but not near so large as the German horses, and therefore they stand up on their short stirrups when they strike. The heydukes usually wear feathers in their caps, according to the number of the enemies they pretend to have killed. Both horse and foot are an excellent militia, very good at a pursuit, or ravaging and plundering a country, but not equal to regular troops in a pitched battle. The women, when they go abroad, wear short cloaks and a veil.

There are four languages spoken in this country, viz. the Hungarian, which, like the people, is of Scythian origin, and has little or no affinity with any European tongue; the German, Slavonian, Wallachian, and Latin. The last is spoken, not only by the better sort, but also by the common people, though very corruptly. The people called *Zigduns* have also a particular jargon.—Christianity was planted in Hungary in the ninth and tenth centuries. In the sixteenth the reformation made a great progress in it; but at present, though the Roman catholics hardly make a fourth part of the inhabitants, their religion is predominant, the Protestants enjoying only a bare toleration. Besides several sects of Protestants, here are also great numbers of the Greek church and Jews; the last pay double taxes of all kinds. Besides Jesuits colleges and other convents, there are several universities for the Roman-catholics. The Lutherans also and Calvinists have their gymnasiums and schools, but under divers restrictions.

As to the traffic of this country, it is almost wholly in the hands of the Greeks and Jews. The exports consist chiefly of wine, horses, cattle, metals, minerals, saffron, wool, and leather. Hungary, in particular, furnishes Austria, and other countries west of it, with vast droves of cattle, as well as variety of excellent wines, of which those of Tokay are reckoned the best. The principal manufactures are those of copper, brass, iron, and other hard wares. Great quantities of brass and iron are exported, wrought and unwrought.

Hungary at first, like most other countries, was divided into many little principalities and states, which at length were united under one head, who had the title of *duke*. The last of these dukes was Geyza: who, becoming a proselyte to Christianity, was baptized; after which he resigned the government to his son Stephen, who took the title of *king*, anno 1000. But
N^o 158.

as the throne was filled by election, though generally out of the same family, the disposal of the crown was disputed between the Turkish and German emperors for near 200 years: but after the year 1527, when Ferdinand archduke of Austria was advanced to the throne, the Austrians found means to influence the elections in such a manner, as to keep the crown in their family till 1687, when it was settled hereditarily on their heirs male; and now, in consequence of an act made by the diet at Presburg in 1723, in case of the failure of heirs-male, it is to descend to females. The states of the kingdom consist of the prelates, the barons, the gentry, and the royal towns. To the first class belong two archbishops, about a dozen bishops, near as many abbots and provosts, with the Pauline and Præmonstratensian Jesuits. To the second, the stadtholder or palatine, who represents the king; the court-judge; the ban or viceroy of Dalmatia, Croatia, and Slavonia; the stadtholder of Transylvania; the great treasurer, the great cup-bearer, the steward of the household, the master of the horse, the lord chamberlain, the captain of the yeomen of the guards, and the grand-marshal of the courts who are styled the great barons, together with the inferior bans or counts and barons. To the third class belong the gentry, some of whom have noble manors, and others only the privileges of nobles. To the fourth class belong the royal free cities, which are not subject to the counts, but hold immediately of the king. The gentry also, who hold of the archbishops and bishops, have the same privileges as the Hungarian nobility. The common people are vassals to the lords, on whose lands they live, whether these lands belong to the crown, the clergy, nobility, or gentry.

The ordinary revenue of this kingdom is said to exceed a million Sterling, arising from the mines, duties on cattle, royal demesnes, salt-works, contributions, customs, &c. The fortifications and garrisons constantly maintained on the frontiers against the Turks, are a great expence to the government. Hungary can easily bring into the field 100,000 men, regulars and militia; for there are 50,000 in actual pay, and the provinces furnish the other 50,000 when they are wanted.

HUNGARY-Water, a distilled water prepared from the tops or flowers of rosemary; so denominated from a queen of Hungary, for whose use it was first made. See PHARMACY.

HUNGER, an uneasy sensation occasioned by long abstinence from food when the body is in a healthy state.—See ABSTINENCE; FASTING; and ANATOMY, n^o 103.

The following useful observations upon hunger or famine are extracted from a paper by Dr Percival in the second volume of the Manchester Transactions.

In famine, life may be protracted (the Doctor observes) with less pain and misery, by a moderate allowance of water. For the acrimony and putrefaction of the humours are obviated by such dilution, the small vessels are kept permeable, and the lungs are furnished with that moisture which is essential to the performance of their functions. Fontanus, a writer of respectable authority in the estimation of Morgagni, relates the history of a woman who obstinately refused to take any sustenance, except
I
twice,

Hunger.

twice, during the space of 50 days, at the end of which period she died. But he adds, that she used water by way of drink, though in small quantity. Redi, who made many experiments (cruel and unjustifiable in my opinion), to ascertain the effects of fasting on fowls, observed, that none were able to support life beyond the ninth day to whom drink was denied; whereas one indulged with water lived more than 20 days.

Hippocrates has observed, that children are more affected by abstinence than young persons; these, more than the middle aged; and the middle aged, more than old men. The power to endure famine, however, must depend no less upon the state of health and strength than on the age of the sufferer. There are also particular constitutions which do not suffer much pain from the calls of hunger. Dr Percival was informed by a young physician from Geneva, that when he was a student at Montpellier, he fasted three nights and four days, with no other refreshment than a pint of water daily. His hunger was keen, but never painful, during the first and second days of his abstinence; and the two following days, he perceived only a faintness when he attempted either bodily or mental exertion: A sense of coldness was diffused over his whole frame, but more particularly affected the extremities. His mind was in a very unusual state of pusillanimity; and he experienced a great tendency to tears whenever he recollected the circumstance which had been the occasion of his fasting. During the whole period, the alvine excretions were suppressed, but not those by the kidneys: and at the close of it, his skin became tinged with a shade of yellow. The first food he took was veal broth; which had something of an intoxicating effect, producing a glow of warmth, and raising his spirits, so as to render him ashamed of his despondency. Perhaps in the case of Sextius Baculus, as recorded in the commentaries of Cæsar*, the extraordinary courage and prowess which he suddenly exerted, might be aided by the exhilarating effect of sustenance, which, under such circumstances, it is probable he would no longer decline. The fact, however, evinces, that neither his sickness nor the sensations of hunger had been so violent as much to impair his strength of body or vigour of mind. Pomponius Atticus, the celebrated friend of Cicero, who put a voluntary end to his life in the 77th year of his age by refusing all food, appears to have experienced ease from his disorder, rather than any acute sufferings by famine. "Sic cum biduo cibo se abstinuisset, subito febris decessit, leviorque morbus esse cepit: tamen propositum nihilo secius perigit. Itaque die quinto, postquam id consilium inierat, decessit" (*Corn. Nepos in Vit. Pomp. Attic.*) From the former circumstance it has been conjectured, that he did not wholly deny himself the use of water, or of some other diluent. But though a few examples of this kind may be adduced, we have the evidence of numerous melancholy facts to show, that the pressure of want is agonizing to the human frame. "I have talked, (says an ingenious writer †), with the captain of a ship, who was one of six that endured it in its extremity, and who was the only person that had not lost his senses when they received accidental relief. He assured me his pains at first were so great, as to be often tempted to eat a part of one of the men who died, and which the rest of his crew actually for some time lived upon:

VOL. VIII. Part II.

Hunger.

He said, that during the continuance of this paroxysm, he found his pains insupportable, and was desirous at one time of anticipating that death which he thought inevitable: But his pains, he said, gradually decreased after the sixth day (for they had water in the ship, which kept them alive so long), and then he was in a state rather of languor than desire; nor did he much wish for food, except when he saw others eating; and that for a while revived his appetite, though with diminished importunity. The latter part of the time, when his health was almost destroyed, a thousand strange images rose upon his mind; and every one of his senses began to bring him wrong information. The most fragrant perfumes appeared to him to have a fetid smell; and every thing he looked at took a greenish hue, and sometimes a yellow. When he was presented with food by the ship's company that took him and his men up, four of whom died shortly after, he could not help looking upon it with loathing instead of desire; and it was not till after four days that his stomach was brought to its natural tone; when the violence of his appetite returned with a sort of canine eagerness."

To those who by their occupations are exposed to such dreadful calamities, it is of serious importance to be instructed in the means of alleviating them. The American Indians are said to use a composition of the juice of tobacco, and the shells of snails, cockles, and oysters calcined, whenever they undertake a long journey, and are likely to be destitute of provisions. It is probable the shells are not burnt into quicklime, but only so as to destroy their tenacity, and to render them fit for levigation. The mass is dried, and formed into pills, of a proper size to be held between the gum and lip, which, being gradually dissolved and swallowed, obtund the sensations both of hunger and of thirst. Tobacco, by its narcotic quality, seems well adapted to counteract the uneasy impressions which the gastric juice makes on the nerves of the stomach when it is empty; and the combination of testaceous powders with it may tend to correct the secretion that is supposed to be the chief agent in digestion, and which, if not acid, is always united with acidity. Certain at least it is, that their operation is both grateful and salutary; for we find the luxurious inhabitants of the East Indies mix them with the betel nut, to the chewing of which they are universally and immoderately addicted. Perhaps such absorbents may be usefully applied, both to divide the doses and to moderate the virulence of the tobacco. For, in the internal exhibition of this plant, much caution is required, as it produces sickness, vertigo, cold clammy sweats, and a train of other formidable symptoms, when taken in too large a quantity. During the time of war, the impressed sailors frequently bring on these maladies, that they may be admitted into the hospitals, and released from servitude. It would be an easy and safe experiment to ascertain the efficacy, and to adjust the ingredients, of the Indian composition mentioned. And there is reason to believe, that the trial would be in some degree successful; for it is known that smoking tobacco gives relief in those habitual pains of the stomach which appear to arise from the irritation of the gastric secretions. The like effect is sometimes produced by increasing the flow of saliva, and swallowing what is thus discharged. And Dr Percival has related

4 U

the

P. Lib. 6.

† Dr Goldsmith's Hist. of the Earth, vol. ii. 126.

Hunger.

the case of a gentleman, who used to masticate, many hours daily, a piece of lead, which being neither hard, friable, nor offensive to the palate, suited his purpose, as he thought, better than any other substance. He continued the custom many years, deriving great ease from it, and suffering no sensible injury from the poisonous quality of the metal. On mentioning this fact to a navy surgeon, the Doctor was told, that the sailors, when in hot climates, are wont to mitigate thirst by rolling a bullet in their mouths. A more innocent mean, the Doctor observes, might be devised; but the efficacy of this evinces, that the salivary glands are for a while capable of furnishing a substitute for drink. When a scarcity of water occurs at sea, Dr Franklin has advised, that the mariners should bathe themselves in tubs of salt-water: For, in pursuing the amusement of swimming, he observed, that, however thirsty he was before immersion, he never continued so afterwards; and that, though he soaked himself several hours in the day, and several days successively in salt-water, he perceived not, in consequence of it, the least taste of saltiness in his mouth. He also further suggests, that the same good effect might perhaps be derived from dipping the sailor's apparel in the sea; and expresses a confidence that no danger of catching cold would ensue.

To prevent the calamity of famine at sea, it has been proposed by Dr Lind, that the powder of salep should constitute part of the provisions of every ship's company. This powder and portable soup, dissolved in boiling water, form a rich thick jelly; and an ounce of each of these articles furnishes one day's subsistence to a healthy full grown man. Indeed, from Dr Percival's experiments it appears, that salep contains more nutritious matter, in proportion to its bulk, than any other vegetable production now used as food. It has the property also of concealing the nauseous taste of salt-water; and consequently may be of great advantage at sea, when the stock of fresh water is so far consumed, that the mariners are put upon short allowance. By the same mucilaginous quality, it covers the offensiveness, and even, in some measure, corrects the acrimony of salted and putrescent meats. But, as a preservative against hunger, salep would be most efficacious combined with an equal weight of beef suet. By swallowing little balls of this lubricating compound at proper intervals, the coats of the stomach would be defended from irritation: and as oils and mucilages are highly nutritive, of slow digestion, and indisposed to pass off by perspiration, they are peculiarly well adapted to support life in small quantities. This composition is superior in simplicity, and perhaps equal in efficacy, to the following one, so much extolled by Avicenna the celebrated Arabian physician; to whom we are indebted for the introduction of rhubarb, cassia, tamarinds, and fenna, into the materia medica. "Take sweet almonds and beef suet, of each one pound; of the oil of violets two ounces; and of the roots of marsh mallows one ounce: bray these ingredients together in a mortar, and form the mass into boluses, about the size of a common nut." Animal fat is singularly powerful in assuaging the most acute sensations of thirst, as appears from the narrative of the sufferings experienced by those who were confined in the black hole at Calcutta. A hundred and forty-six persons, exhausted by fatigue

and military duty, were there thrust together into a chamber of 18 cubic feet, having only two windows, strongly barred with iron, from which, in a close sultry night, and in such a climate as that of Bengal, little or no circulation of fresh air could be enjoyed. In a few minutes, these unhappy wretches fell into so profuse a perspiration, that an idea can hardly be formed of it; and this was succeeded by a raging thirst, which increased in proportion as the body was drained of its moisture. Water! Water! became the universal cry; and an old soldier on the outside, through pity, furnished them with a few skinfuls of it. But these scanty supplies, like sprinklings on the fire, served only to feed and increase the flame. From this experience of its effects, Mr Holwell, their chief, determined to drink no more; and kept his mouth moist by sucking the perspiration out of his shirt sleeves, and catching the drops as they fell from his head and face. "You cannot imagine (says he) how unhappy I was if any of them escaped me." He came into the prison without his coat, the season being too hot to bear it: and one of his miserable companions, observing the expedient he had hit upon of allaying his thirst, robbed him from time to time of a considerable part of his store. This plunderer, whom he found to be a young gentleman in the service of the East India Company, afterwards acknowledged, that he owed his life to the many comfortable draughts which he derived from him. Before Mr Holwell adopted this mode of relief, he had attempted, in an ungovernable fit of thirst, to drink his own urine: but it was so intensely bitter, that a second taste could not be endured; whereas, he assures us, no Bristol water could be more soft and pleasant than his perspiration. And this, we may presume, consisted chiefly of animal fat, melted by excessive heat, and exuding from the cellular membrane through the pores of the skin.

Persons who have been accustomed to animal food, are soon reduced when supplied only with the farinacea. Several years ago, to determine the comparative nutritive powers of different substances, an ingenious young physician, as Dr Percival informs us, made a variety of experiments on himself, to which he unfortunately fell a sacrifice. He lived a month upon bread and water; and under this regimen of diet he every day diminished much in his weight. But in 1784, a student of physic at Edinburgh confined himself for a longer space of time to a pint of milk and half a pound of white bread daily: And he assured our author, that he passed through the usual labours of study and exercise without feeling any decay of health or strength, and without any sensible loss of bulk. The cutaneous, urinary, and alvine excretions, were very scanty during the whole period; and the discharge of feces occurred only once in a week. In this case the oily and coagulable parts of the milk probably furnished a larger proportion of aliment, and at the same time contributed to check the waste by perspiration and other discharges; for oleaginous substances are retained long in the body by their viscosity. Dr Russel, in his natural History of Aleppo, relates, that in those seasons when oil abounds, the inhabitants, by indulgence in it, are disposed to fever, and affected with infarctions of the lungs; maladies which indicate both retention and obstruction. Milk has been

Hunger.

suf-

Hunger. suspected by some of producing similar effects, though in a slighter degree; and the free use of it has been on this account forbidden to asthmatics.

Gum arabic might be a good substitute for salep in the composition already recommended; and as it will give such firmness to the mass, as to require manducation, the saliva, by this means separated and carried into the stomach, would further contribute to assuage the sensations both of hunger and of thirst. See *Gum-Arabic*. This gum, combined with sugar and the whites of eggs, has been lately extolled in France, under the name of *patigumo*, as a remedy for catarrhal defluxions. Dr Percival has seen cakes made of these ingredients, and thinks they might very well be applied to the purpose of obviating hunger. They are not perishable in the hottest climates, may be carried about the person with convenience, and though very tough are pleasant to the taste. In the formula by which they are made, the proportion of sugar is too large, and that of gum arabic too small, if the mass be intended to assuage the cravings of appetite. According to our author's information, the receipt is as follows. "Take of fine sugar four ounces, and of gum arabic one ounce: Levigate them well together; and add half an ounce of rose water, and of the white of eggs a sufficient quantity."

In our attempts to recover those who have suffered under the calamities of famine, great circumspection is required. Warmth, cordials, and food, are the means to be employed; and it is evident that these may prove too powerful in their operation, if not administered with caution and judgment. For the body, by long fasting, is reduced to a state of more than infantile debility; the minuter vessels of the brain, and of the other organs, collapse for want of fluids to distend them; the stomach and intestines shrink in their capacity; and the heart languidly vibrates, having scarcely sufficient energy to propel the scanty current of blood. Under such circumstances, a proper application of heat seems an essential measure, and may be effected by placing on each side a healthy man in contact with the patient. Pediluvia or fomentations may also be used with advantage. The temperature of these should be lower than that of the human body, and gradually increased according to the effects of their stimulus. New milk, weak broth, or water gruel, ought to be employed both for the one and the other; as nutriment may be conveyed into the system this way, by passages probably the most pervious in a state of fasting, if not too long protracted. "A lad at New-market†, a few years ago, having been almost starved in order that he might be reduced to a proper weight for riding a match, was weighed at nine o'clock in the morning, and again at ten; and he was found to have gained near thirty ounces in weight in the course of an hour, though he had only drank half a glass of wine in the interval. The wine probably stimulated the action of the nervous system, and incited nature, exhausted by abstinence, to open the absorbent pores of the whole body, in order to suck in some nourishment from the air." But no such absorption as this can be expected in a state of extreme weakness and emaciation gradually induced; because the lymphatics must partake of the general want of tone and energy. And notwithstanding the salutary effects of wine in the case of the jockey,

who, it is likely, had been reduced by sweating as well as by abstinence, such a stimulant might prove dangerous, and even fatal in other cases. It appears safer therefore to advise the exhibition of cordials in very small doses, and at first considerably diluted. Slender wine-whey will perhaps best answer this purpose; and afford, at the same time, an easy and pleasant nourishment. When the stomach has been a little strengthened, an egg may be mixed with the whey, or administered under some other agreeable form. The yolk of one was, to Cornaro, sufficient for a meal; and the narrative of this noble Venetian, in whom a fever was excited by the addition of only two ounces of food to his daily allowance, shows, that the return to a full diet should be conducted with great caution, and by very slow gradations.

HUNNS, a fierce and savage nation, who formerly inhabited that part of Sarmatia bordering on the Paulus Mæotis and the Tanais, the ancient boundary between Europe and Asia. Their country, as described by Procopius, lay north of mount Caucasus, which, extending from the Euxine to the Caspian Seas, parts Asiatic Sarmatia from Colchis, Iberia, and Albania; lying on the isthmus between the two seas above mentioned. Here they resided, unknown to other nations, and themselves ignorant of other countries, till the year 376. At this time, an hind pursued by the hunters, or, according to some authors, an ox stung by a gad-fly, having passed the marsh, was followed by some Hunns to the other side, where they discovered a country much more agreeable than their own. On their return, having acquainted their countrymen with what they had seen, the whole nation passed the marsh, and, falling upon the Alans who dwelt on the banks of the Tanais, almost exterminated them. They next fell upon the Ostrogoths, whom they drove out of their country, and forced to retire to the plains between the Borysthenes and the Tanais, now known by the name of *Podolea*. Then attacking the Visigoths, they obliged them to shelter themselves in the most mountainous parts of their country; till at last the Gothick nations, finding it impossible to withstand such an inundation of barbarians, obtained leave from the emperor Valens to settle in Thrace.

The Hunns thus became masters of all the country between the Tanais and Danube in 376, where they continued quietly till the year 388, when great numbers of them were taken into the pay of Theodosius I. but, in the mean time, a party of them, called the *Nephthalite* or *White Hunns*, who had continued in Asia, over-ran all Mesopotamia, and even laid siege to Edessa, where they were repulsed with great slaughter by the Romans. The European Hunns frequently passed the Danube, committing the greatest ravages in the western empire; sometimes they fell upon the eastern provinces, where they put all to fire and sword. They were often defeated and repulsed by the Romans, but the empire was now too weak to subdue or confine them from making excursions; so that they continued to make daily encroachments, and became every day more formidable than before. In 441, the Hunns, under Attila, threatened the western empire with total destruction. This monarch, having made himself master of all the northern countries from the confines of Persia to the banks of the Rhine, invaded Mæsia, Thrace,

Hunger. Thrace, and Illyricum; where he made such progress, that the emperor, not thinking himself safe in Constantinople, withdrew into Asia. Attila then broke into Gaul; where he took and destroyed several cities, massacring the inhabitants with the greatest cruelty. At last he was driven out with great slaughter by Aetius the Roman general and Theodoric king of the Goths, and could never afterwards make any great progress. About the year 452 or 453 Attila died, and his kingdom was immediately split into a number of small ones by his numerous children, who waged perpetual war with each other. The Hunns then ceased to be formidable, and became daily less able to cope with the other barbarous nations whom Attila had kept in subjection. Still, however, their dominion was considerable; and in the time of Charles the Great they were masters of Transylvania, Walachia, Servia, Carniola, Carinthia, and the greater part of Austria, together with Bosnia, Slavonia, and that part of Hungary which lies beyond the Danube. In the year 776, while Charles was in Saxony, two princes of the Hunns, Caganus and Jugunus, sent ambassadors to him, desiring his friendship and alliance. Charles received them with extraordinary marks of friendship, and readily complied with their request. However, they entered, not long after, into an alliance with Tassila duke of Bavaria, who had revolted from Charles, and raised great disturbances in Germany. Charles dissembled his resentment till he had entirely reduced Bavaria, when he resolved to revenge himself on the Hunns for those succours they had underhand given to his enemy. Accordingly, he ordered levies to be made throughout his dominions; and having by that means assembled a very numerous army, he divided it into two bodies, one of which he commanded himself, and the other he committed to the care of his generals. The two armies entered the country of the Hunns at different places, ravaged their country far and near, burnt their villages, and took all their strong holds. This he continued for eight years, till the people were almost totally extirpated; nor did the Hunns ever afterwards recover themselves, or appear as a distinct nation.

There were two different nations that went by the name of *Hunns*; the Nephthalite or White Hunns, and the Sarmatian or Scythian Hunns. The former inhabited a rich country, bordering to the north on Persia, and at a great distance from the Sarmatian or Scythian Hunns, with whom they had no intercourse nor the least resemblance either in their persons or manners. They were a powerful nation, and often served against the Romans in the Persian armies; but in the reign of the emperor Zeno, being provoked by Perozes king of Persia laying claim to part of their country, they defeated the Persians in two pitched battles, slew their king, over-ran all Persia, and held it in subjection for the space of two years, obliging Cabades, the son and successor of Perozes, to pay them a yearly tribute. These Hunns, called by the writers of those times the *white Hunns*, did not wander, like the others, from place to place; but, contented with their own country, which supplied them with all necessities, they lived under a regular government, subject to one prince, and seldom made inroads, unless provoked either into the Persian or Roman territories.

They lived according to their own laws, and dealt up-
rightly with one another, as well as with the neighbouring people. Each of their great men used to choose 20 or more companions to enjoy with him his wealth, and partake of all his diversions; but, upon his decease, they were all buried with him in the same grave. This custom favours of barbarity; but in every other respect, the Nephthalite were a far more civilized nation than the Scythian Hunns, who, breaking into the empire, filled most of the provinces of Europe with blood and slaughter.

The latter were, according to Ammianus Marcellinus, a savage people, exceeding in cruelty the most barbarous nations. They begin to practise their cruelty, says Jornandes, upon their own children the very first day they come into the world, cutting and mangling the cheeks of their males, to prevent the growth of hair, which they must have looked upon, contrary to the sentiments of other nations, as unbecoming and unmanly. They had, perhaps, in this practice another view, which Jornandes seems to insinuate elsewhere, viz. to strike terror into the enemy with their countenances, thus deformed and covered with scars. They had no other food but roots and raw meat, being quite unacquainted with the use of fire, and no houses at all, not even huts; but lived constantly exposed to the air in the woods, and on the mountains, where, from their infancy, they were inured to hunger, thirst, and all manner of hardships: nay, they had such an aversion to houses, which they called the *sepulchres of the living*, that, when they went into other countries, they could hardly be prevailed upon to come within the walls of any house, not thinking themselves safe when shut up and covered. They used even to eat and sleep on horseback, scarce ever dismounting; which, in all likelihood, induced Zosimus to write, that the Hunns could not walk. They covered their nakedness with goats skins, or the skins of a sort of mice sewed together. Day and night were indifferent to them, as to buying, selling, eating, and drinking. They had no law, nor any kind of religion; but complied with their inclinations, whatever they prompted them to, without the least restraint, or distinction between good and evil. In war, they began the battle with great fury, and an hideous noise: but if they met with a vigorous opposition, their fury began to abate after the first onset; and when once put into disorder, they never rallied, but fled in the utmost confusion. They were quite unacquainted with the art of besieging towns; and authors observe, that they never attacked the enemy's camp. They were a faithless nation, and thought themselves no longer bound by the most solemn treaties, than they found their advantage in observing them. Hence we often find them, upon the least prospect of obtaining more advantageous conditions, breaking into the Roman empire, in defiance of the most solemn oaths and engagements. Several corps of Hunns, after their coming into Europe, served in the Roman armies against the Goths and other barbarous nations; nay, they were ready, for hire, to fight against each other, being blind to every other regard and consideration.

HUNGERFORD, a town of Berkshire in England, seated on the river Kennet, in a low and watery soil. It is a great thoroughfare in the Bath and Bristol

Hunnin-
guen,
Hunter.

hol road, 65 miles from London; and was formerly called *Ingleford-Charnamstreet*. The constable of this town, who is chosen annually, is lord of the manor, which he holds immediately of the crown. They have a horn here which holds about a quart, and appears by an inscription on it to have been given by John of Gaunt, together with a grant of the royal fishery, in a part of the river which abounds with good trouts and *cray fish*. Here is a market on Wednesdays, and fair in August.

HUNNINGUEN, a town of Germany, in Alsace, and in Suntgaw, subject to the French; seated on the Rhine, and fortified by Vauban. E. Long. 11. 40. N. Lat. 47. 42.

HUNTER, a name given to a horse qualified to carry a person in the chace. The shape of the horse designed for this service, should be strong and well knit together, as the jockeys express it. Irregular or unequal shapes in these creatures are always a token of weakness. The inequalities in shape which show a horse improper for the chace, are the having a large head and a small neck, a large leg and a small foot, and the like. The head of the hunter should indeed always be large, but the neck should also be thick and strong to support it. The head should be lean, the nostrils wide, and the windpipe straight.

The hunter, in order to his behaving well in the field, ought to have great care and indulgence in the stable: he ought to have as much rest and quiet as may be, to be kept well supplied with good meat, clean litter, and fresh water by him; he should be often dressed, and suffered to sleep as much as he pleases. He should be so fed, that his dung may be rather soft than hard, and it must be of a bright and clean colour. All this may be easily managed by the continual observance and change of his food, as occasion requires. After his usual scourings he should have exercises and mashes of sweet-malt, or bread and beans; or wheat and beans mixed together, are to be his best food, and beans and oats his worst.

Some very great sportsmen are for keeping their horses out at grass all the buck-hunting season, never taking them up into the stable at all, but allowing them in the field as much oats with their grass as they will eat. The horse may be thus rid three days in the week for the whole season, and never damaged by it, nor ever showing any marks of harm afterwards.

The whole shape of a horse intended for a hunter, should be this: The ears should be small, open, and pricked; or though they be somewhat long, yet if they stand up erect and bold like those of a fox, it is a sign of toughness or hardiness. The forehead should be long and broad, not flat; or, as it is usually termed, *mare-faced*, but rising in the middle like that of a hare; the feather should be placed above the eye, the contrary being thought by some to threaten blindness. The eyes should be full, large, and bright; the nostrils not only large, but looking red and fresh within; for an open and fresh nostril is always esteemed a sign of a good wind. The mouth should be large, deep in the wicks, and hairy. The wind-pipe should be large, and appear straight when he bridles his head; for if, on the contrary, it bends like a bow on his bridling, it is not formed for a free passage of the breath. This defect in a horse is expressed among the dealers by the

phrase *cock-thropped*. The head should be so set on to the neck, that a space may be felt between the neck and the chine; when there is no such space, the horse is said to be bull-necked; and this is not only a blemish in the beauty of the horse, but it also occasions his wind not to be so good. The crest should be strong, firm, and well risen; the neck should be straight and firm, not loose and pliant; the breast should be strong and broad, the ribs round like a barrel, the fillets large, the buttocks rather oval than broad, the legs clean, flat, and straight; and, finally, the mane and tail ought to be long and thin, not short and bushy, the last being counted a mark of dulness. When a hunter is thus chosen, and has been taught such obedience, that he will readily answer to the rider's signals both of the bridle and hand, the voice, the calf of the leg, and the spurs; that he knows how to make his way forward, and has gained a true temper of mouth, and a right placing of his head, and has learned to stop and to turn readily, if his age be sufficiently advanced, he is ready for the field. It is a rule with all staunch sportsmen, that no horse should be used in hunting till he is full five years old; some will hunt them at four, but the horse at this time is not come up to his true strength and courage, and will not only fail at every tough trial, but will be subject to strains and accidents of that kind, much more than if he were to be kept another year first, when his strength would be more confirmed.

When the hunter is five years old, he may be put to grass from the middle of May till Bartholomew-tide; for the weather between these is so hot, that it will be very proper to spare him from work. At Bartholomew-tide, the strength of the grass beginning to be nipped by frosts and cold dews, so that it is apt to engender crudities in the horse, he should be taken up while his coat is yet smooth and sleek and put into the stable. When he is first brought home, he should be put in some secure and spacious place, where he may evacuate his body by degrees, and be brought not all at once to the warm keeping; the next night he may be stabled up. It is a general rule with many not to clothe and stable up their horses till two or three days after they are taken from grass, and others who put them in the stable after the first night, yet will not dress and clothe them till three or four days afterward; but all this, except the keeping the horse one day in a large and cool place, is needless caution.

There is a general practice among the grooms, in many places, of giving their hunters wheat-straw as soon as they take them up from grass. They say they do this to take up their bellies; but there seems much reason to disapprove of this. The change is very violent, and the nature of the straw so heating and drying, that there seems great reason to fear that the astringent nature of it would be prejudicial, more than is at first perceived. It is always found that the dung is hard after this food, and is voided with pain and difficulty, which is in general very wrong for this sort of horse. It is better therefore to avoid this straw-feeding, and to depend upon moderate airing, warm cloathing, and good old hay, and old corn, than to have recourse to any thing of this kind.

When the horse has evacuated all his grass, and has been properly shod, and the shoes have had time to

Hunter.

settle.

Hunter. settle to his feet, he may be ridden abroad, and treated in this manner: the groom ought to visit him early in the morning, at five o'clock in the long days, and at six in the short ones; he must then clean out the stable, and feel the horse's neck, flank, and belly, to find the state of his health. If the flank feels soft and flabby, there is a necessity of good diet to harden it, otherwise any great exercise will occasion swellings and goutiness in the heels. After this examination, a handful or two of good old oats, well sifted, should be given him; this will make him have more inclination to water, and will also make the water sit better on his stomach, than if he drank fasting. After this he is to be tied up and dressed. If in the doing of this he opens his mouth, as if he would bite, or attempts to kick at the person, it is a proof that the teeth of the curry-comb are too sharp, and must be filed blunter. If after this he continues the same tricks, it is through wantonness, and he should be corrected for it with the whip. The intent of currying being only to raise the dust, this is to be brushed off afterwards with a horse-tail nailed to a handle, or any other light brush. Then he is to be rubbed down with the brush, and dusted a second time; he should then be rubbed over with a wet hand, and all the loose hairs, and whatever foulness there is, should be picked off. When this is done, and he is wiped dry as at first, a large saddle-cloth is to be put on, reaching down to the spurring place; then the saddle is to be put on, and a cloth thrown over it that he may not take cold: then rub down his legs, and pick his feet with an iron picker, and let the mane and tail be combed with a wet mane-comb. Lastly, it is a custom to spurt some beer in his mouth just before the leading him out of the stable. He should then be mounted, and walked a mile at least to some running water, and there watered; but he must only be suffered to take about half his water at one drinking.

It is the custom of many to gallop the horse at a violent rate as soon as he comes out of the water; but this is extremely wrong for many reasons. It endangers the breaking a horse's wind more than any other practice, and often has been the occasion of bursting very good horses. It uses them also to the disagreeable trick we find in many horses, of running away as soon as ever they come out of the water: and with some it makes them averse to drinking, so that they will rather endure thirst, and hurt themselves greatly by it, than bring on the violent exercise which they remember always follows it. The better way is to walk him a little after he is out of the water, then put him to a gentle gallop for a little while, and after this to bring him to the water again. This should be done three or four times, till he will not drink any more. If there is a hilly place near the watering place, it is always well to ride up to it; if otherwise, any place is to be chosen where there is free air and sun. That the creature may enjoy the benefit of this, he is not to be galloped, but walked about in this place an hour, and then taken home to the stable. The pleasure the horse himself takes in these airings when well managed is very evident; for he will gape, yawn, and shrug up his body: and in these, whenever he would stand still to stale, dung, or listen to any noise, he is not to be

hindered from it, but encouraged in every thing of this kind. **Hunter.**

The advantages of these airings are very evident; they purify the blood, teach the creature how to make his breathing agree with the rest of the motions of his body, and give him an appetite to his food, which hunters and racers that are kept stalled up are otherwise very apt to lose. On returning from airing, the litter of the stable should be fresh, and by stirring this and whistling, he will be brought to stale. Then he is to be led to his stall, and tied up, and again carefully rubbed down; then he should be covered with a linen cloth next his body, and a canvas one over that, made to fit him, and reaching down to his legs. This, as the duke of Newcastle observes, is a custom which we learned of the Turks, who are of all people the most nice and careful of their horses. Over this covering there should be put a body-cloth of six or eight straps; this keeps his belly in shape, and does not hurt him. This cloathing will be sufficient while the weather is not very sharp; but in severe seasons, when the hair begins to rise and start in the uncovered parts, a woollen cloth is to be added, and this will always prove fully sufficient.

Different horses, and different seasons, make variety of the degree of cloathing necessary; but there always is an obvious rule to point out the necessary changes, the roughness of the coat being a mark of the want of cloathing, and the smoothness of it a proof that the cloathing is sufficient. Therefore if at any time the hair is found to start, it is a notice that some farther cloathing is to be added.

If the horse sweat much in the night, it is a sign that he is over fed and wants exercise; this therefore is easily remedied. An hour or more after the horse is come in from his airing, the groom should give him a wisp of clean hay, making him eat it out of his hand; after this let the manger be well cleaned out, and a quartern of oats clean sifted be given him. If he eats up this with an appetite, he should have more given him; but if he is slow and indifferent about it, he must have no more. The business is to give him enough, but not to cloy him with food.

If the horse gets flesh too fast on this home feeding, he is not to be stinted to prevent it, but only his exercise increased; this will take down his flesh, and at the same time give him strength and wind. After the feeding in the morning is over the stable is to be shut up, only leaving him a little hay on his litter. He need be no more looked at till one o'clock, and then only rubbed down, and left again to the time of his evening watering, which is four o'clock in the summer and three in the winter. When he has been watered, he must be kept out an hour or two, or more if necessary, and then taken home and rubbed as after the morning watering. Then he is to have a feed of corn at six o'clock, and another at nine at night; and being then cleaned, and his litter put in order, and hay enough left for the night, he is to be left till morning. This is the direction for one day, and in this manner he is to be treated every day for a fortnight; at the end of which time his flesh will be so hardened, his wind so improved, and his mouth so quickened, and his gallop brought to so good a stroke, that he will be

Hunter.

fit to be put to moderate hunting. During the time that he is used to hunting, he must be ordered on his days of rest exactly as he is directed for the fortnight when he is in preparation; but as his exercise is now greatly increased, he must be allowed a more strengthening food, mixing some old split beans at every feeding with his oats.

And if this is not found to be sufficient, the following bread must be given: let two pecks of old beans and one peck of wheat be ground together, and made into an indifferently fine meal; then knead it into dough with some warm water and a good quantity of yeast; let it lie a time that it may rise and swell, which will make the bread the lighter; then make it into loaves of a peck each, and let it be baked in a slow oven, that it may be thoroughly done without being burnt; when it is taken out of the oven, it must be set bottom upwards to cool: when it is one day old the crust is to be chipped off, and the crumb given him for food. When this is ready, he should have some of it at least once in the day; but it is not to be made the only food, but some feeds are to be of oats alone, some of oats and this bread, and some of oats and beans mixed together. The making a variety in this manner being the best of all methods of keeping up the appetite, which is often apt to fail.

The day before the horse is to hunt, he must have no beans, because they are hard of digestion, but only some oats with this bread; or if he will be brought to eat the bread alone, that will be best of all. His evening feed should on this day be somewhat earlier than usual; and after this he is only to have a wisp of hay out of the groom's hand till he return from hunting.

HUNTER (Dr William), a celebrated anatomist and physician, was born on the 23d of May 1718, at Kilbride in the county of Lanerk in Scotland. He was the seventh of ten children of John and Agnes Hunter, who resided on a small estate in that parish called *Long Calderwood*, which had been long in the possession of his family. His great grandfather by his father's side, was a younger son of Hunter of Hunterston, chief of the family of that name. At the age of fourteen his father sent him to the college of Glasgow. In this seminary he passed five years; and by his prudent behaviour and diligence acquired the esteem of the professors, and the reputation of being a good scholar. His father had designed him for the church; but the idea of subscribing to articles of faith was so repugnant to the liberal mode of thinking he had already adopted, that he felt an insuperable aversion to his theological pursuits. In this state of mind he happened to become acquainted with Dr Cullen, the late celebrated professor at Edinburgh, who was then just established in practice at Hamilton under the patronage of the duke of Hamilton. Dr Cullen's conversation soon determined him to lay aside all thoughts of the church, and to devote himself to the profession of physic. His father's consent having been previously obtained, Mr Hunter in 1737 went to reside with Dr Cullen. In the family of this excellent friend and preceptor he passed nearly three years; and these, as he has been often heard to acknowledge, were the happiest years of his life. It was then agreed, that he should go and prosecute his medical studies at Edinburgh and Lon-

don, and afterwards return to settle at Hamilton in partnership with Dr Cullen. He accordingly set out for Edinburgh in November 1740; and continued there till the following spring, attending the lectures of the medical professors, and amongst others those of the late Dr Alexander Monro, who many years afterwards, in allusion to this circumstance, styled himself his *old master*.

Mr Hunter arrived in London in the summer of 1741, and took up his residence at Mr, afterwards Dr, Smellie's, who was at that time an apothecary in Pall Mall. He brought with him a letter of recommendation to his countryman Dr James Douglas, from Mr Foulis printer at Glasgow, who had been useful to the Doctor in collecting for him different editions of *Horace*. Dr Douglas was then intent on a great anatomical work on the bones, which he did not live to complete, and was looking out for a young man of abilities and industry whom he might employ as a dissector. This induced him to pay particular attention to Mr Hunter; and finding him acute and sensible, he desired him to make him another visit. A second conversation confirmed the doctor in the good opinion he had formed of Mr Hunter; and without any farther hesitation he invited him into his family to assist in his dissections and to superintend the education of his son.—Mr Hunter having accepted Dr Douglas's invitation, was by his friendly assistance enabled to enter himself as a surgeon's pupil at St George's Hospital under Mr James Wilkie, and as a dissecting pupil under Dr Frank Nichols who at that time taught anatomy with considerable reputation. He likewise attended a course of lectures on experimental philosophy by Dr Desaguliers. Of these means of improvement he did not fail to make a proper use. He soon became expert in dissection, and Dr Douglas was at the expence of having several of his preparations engraved. But before many months had elapsed, he had the misfortune to lose this excellent friend.—The death of Dr Douglas, however, made no change of the situation of our author. He continued to reside with the Doctor's family, and to pursue his studies with the same diligence as before.

In 1743 he communicated to the Royal Society an essay on the Structure and Diseases of articulating Cartilages. This ingenious paper, on a subject which till then had not been sufficiently investigated, affords a striking testimony of the rapid progress he had made in his anatomical inquiries. As he had it in contemplation to teach anatomy, his attention was directed principally to this object; and it deserves to be mentioned as an additional mark of his prudence, that he did not precipitately engage in this attempt, but passed several years in acquiring such a degree of knowledge and such a collection of preparations, as might insure him success. Dr Nichols, to whom he communicated his scheme, and who declined giving lectures about that time in favour of the late Dr Lawrence, did not give him much encouragement to prosecute it. But at length an opportunity presented itself for the display of his abilities as a teacher. A society of navy surgeons had an apartment in Covent Garden, where they engaged the late Mr Samuel Sharpe to deliver a course of lectures on the operations of surgery. Mr Sharpe continued to repeat this course,

till

Hunter.

Hunter. till finding that it interfered too much with his other engagements, he declined the task in favour of Mr Hunter; who gave the society so much satisfaction, that they requested him to extend his plan to anatomy, and at first he had the use of their room for his lectures. This happened in the winter of 1746. He is said to have experienced much solicitude when he began to speak in public: but the applause he met with soon inspired him with courage; and by degrees he became so fond of teaching, that for many years before his death he was never happier than when employed in delivering a lecture. The profits of his two first courses were considerable; but by contributing to the wants of different friends, he found himself at the return of the next season obliged to defer his lectures for a fortnight, merely because he had not money enough to defray the necessary expence of advertisements.

In 1747, he was admitted a member of the corporation of surgeons; and in the spring of the following year, soon after the close of his lectures, he set out in company with his pupil, Mr James Douglas, on a tour through Holland to Paris. His lectures suffered no interruption by this journey, as he returned to England soon enough to prepare for his winter-course, which began about the usual time.

At first he practised both surgery and midwifery; but to the former of these he had always an aversion. His patron, Dr James Douglas, had acquired considerable reputation in midwifery; and this probably induced Mr Hunter to direct his views chiefly to the same line of practice. His being elected one of the surgeon-men-midwives, first to the Middlesex, and soon afterwards to the British Lying-in Hospital, assisted in bringing him forward in this branch of his profession, in which he was recommended by several of the most eminent surgeons of that time, who respected his anatomical talents and wished to encourage him. But these were not the only circumstances that contributed to his success. He owed much to his abilities, and much to his person and manner, which eminently qualified him for the practice of midwifery.

In 1750, he seems to have entirely relinquished his views in surgery; as in that year he obtained the degree of Doctor of Physic from the university of Glasgow, and began to practise as a physician. About this time he quitted the family of Mrs Douglas, and went to reside in Jermyn-street. In the summer of 1751 he revisited his native country, for which he always retained a cordial affection. His mother was still living at Long Calderwood, which was now become his property by the death of his brother James. Dr Cullen, for whom he always entertained a sincere regard, was then established at Glasgow, and had acquired considerable reputation both as a practitioner and teacher of physic; so that the two friends had the pleasure of being able to congratulate each other on their mutual prosperity. During this visit he showed his attachment to his little paternal inheritance, by giving many instructions for repairing and improving it, and for purchasing any adjoining lands that might be offered for sale. After this journey to Scotland, to which he devoted only a few weeks, he was never absent from London, unless his professional engagements, as sometimes happened, required his attendance at a distance from the capital.

No 158.

Hunter. In 1755, on the resignation of Dr Layard, one of the physicians of the British lying-in hospital, we find the governors of that institution voting their "thanks to Dr Hunter for the services he had done the hospital, and for his continuing in it as one of the physicians:" so that he seems to have been established in this office without the usual form of an election. The year following he was admitted a licentiate of the Royal College of Physicians. Soon afterwards he was elected a member of the Medical Society; and to the *Observations and Inquiries* published by that society, he at different periods contributed several valuable papers.

In 1762, we find him warmly engaged in controversy, supporting his claim to different anatomical discoveries, in a work intitled *Medical Commentaries*, the style of which is correct and spirited. As an excuse for the tardiness with which he brought forth this work, he observes in his introduction, that it required a good deal of time, and he had little to spare; that the subject was unpleasant, and therefore he was very seldom in the humour to take it up. In this publication he confined himself chiefly to a dispute with the present learned professor of anatomy at Edinburgh, concerning injections of the testicle, the ducts of the lacrymal gland, the origin and use of the lymphatic vessels, and absorption by veins. He likewise defended himself against a reproach thrown upon him by professor Monro senior, by giving a concise account of a controversy he was involved in with Mr Pott concerning the discovery of the Hernia Congenita. It was not long before Mr Pott took occasion to give the public his account of the dispute; and, in reply, Dr Hunter added a supplement to his commentaries. No man was ever more tenacious than Dr Hunter of what he conceived to be his anatomical rights. This was particularly evinced in the year 1780, when his brother communicated to the Royal Society a discovery he had made 25 years before, relative to the structure of the placenta, the communication between it and the uterus, and the vascularity of the spongy chorion. At the next meeting of the society, a letter was read, in which Dr Hunter put in his claim to the discovery in question. This letter was followed by a reply from Mr John Hunter, and here the dispute ended.

In 1762, when the queen became pregnant, Dr Hunter was consulted: and two years afterwards he had the honour to be appointed physician extraordinary to her majesty.

About this time his avocations were so numerous, that he became desirous of lessening his fatigue; and having noticed the ingenuity and assiduous application of the late Mr William Hewson, F. R. S. who was then one of his pupils, he engaged him first as an assistant, and afterwards as a partner, in his lectures. This connection continued till the year 1770; when some disputes happened, which terminated in a separation. Mr Hewson was succeeded in the partnership by Mr Cruikshank, whose anatomical abilities are deservedly respected.

In 1767, Dr Hunter was elected a fellow of the Royal Society: and in the year following communicated to that learned body observations on the bones, commonly supposed to be elephants bones, which have been found near the river Ohio in America. This

was

Hunter

was not the only subject of natural history on which our author employed his pen; for in a subsequent volume of the Philosophical Transactions, we find him offering his remarks on some bones found in the rock of Gibraltar, and which he proves to have belonged to some quadruped. In the same work, likewise, he published an account of the nyl-ghau, an Indian animal not described before. In 1768, Dr Hunter became a fellow of the Society of Antiquaries; and the same year, at the institution of a Royal Academy of Arts, he was appointed by his majesty to the office of professor of anatomy. This appointment opened a new field for his abilities; and he engaged in it, as he did in every other pursuit of his life, with unabating zeal. He now adapted his anatomical knowledge to the objects of painting and sculpture, and the novelty and justness of his observations proved at once the readiness and extent of his genius. In January 1781, he was unanimously elected to succeed the late Dr John Fothergill as president of the Medical Society. As his name and talents were known and respected in every part of Europe, so the honours conferred on him were not limited to his own country. In 1780, the Royal Medical Society at Paris elected him one of their foreign associates; and in 1782, he received a similar mark of distinction from the Royal Academy of Sciences in that city.

The most splendid of Dr Hunter's medical publications was the Anatomy of the Human Gravid Uterus. The appearance of this work, which had been begun so early as the year 1751 (at which time 10 of the 34 plates it contains were completed), was retarded till the year 1775, only by the author's desire of sending it into the world with fewer imperfections. This great work is dedicated to the king. In his preface to it, we find the author very candidly acknowledging, that in most of the dissections he had been assisted by his brother Mr John Hunter, "whose accuracy (he adds) in anatomical researches is so well known, that to omit this opportunity of thanking him for that assistance would be in some measure to disregard the future reputation of the work itself." He likewise confesses his obligations to the ingenious artists who made the drawings and engravings; "but particularly to Mr Strange, not only for having by his hand secured a sort of immortality to two of the plates, but for having given his advice and assistance in every part with a steady and disinterested friendship. An anatomical description of the gravid uterus was a work which Dr Hunter had in contemplation to give the public. He had likewise long been employed in collecting and arranging materials for a history of the various concretions that are formed in the human body. Amongst Dr Hunter's papers have been found two introductory lectures, which are written out so fairly, and with such accuracy, that he probably intended no farther correction of them before they should be given to the world. In these lectures Dr Hunter traces the history of anatomy from the earliest to the present times, along with the general progress of science and the arts. He considers the great utility of anatomy in the practice of physic and surgery; gives the ancient divisions of the different substances composing the human body, which for a long time prevailed in anatomy; points out the most advantageous mode of cultivating this branch of natural knowledge; and con-

Vol. VIII. Part II.

cludes with explaining the particular plan of his own lectures. Besides these manuscripts, he has also left behind him a considerable number of cases of dissection: mostly relating to pregnant women.

The same year in which the Tables of the Gravid Uterus made their appearance, Dr Hunter communicated to the Royal Society an Essay on the Origin of the Venereal Disease. In this paper he attempted to prove, that this dreadful malady was not brought from America to Europe by the crew of Columbus, as had been commonly supposed, although it made its first appearance about that period. After this paper had been read to the Royal Society, Dr Hunter, in a conversation with the late Dr Musgrave, was convinced that the testimony on which he placed his chief dependence was of less weight than he had at first imagined, as many of Martyr's letters afford the most convincing proofs of their having been written a considerable time after the period of their dates. He therefore very properly laid aside his intention of giving his essay to the public. In the year 1777 Dr Hunter joined with Mr Watson in presenting to the Royal Society a short account of the late Dr Maty's illness, and of the appearances on dissection; and the year following he published his Reflections on the Section of the Symphysis Pubis.

We must now go back a little into the order of time to describe the origin and progress of Dr Hunter's museum, without some account of which the history of his life would be very incomplete.

When he began to practise midwifery, he was desirous of acquiring a fortune sufficient to place him in easy and independent circumstances. Before many years had elapsed, he found himself in possession of a sum adequate to his wishes in this respect; and this he set apart as a resource of which he might avail himself whenever age or infirmities should oblige him to retire from business. After he had obtained this competency, as his wealth continued to accumulate, he formed a laudable design of engaging in some scheme of public utility, and at first had it in contemplation to found an anatomical school in this metropolis. For this purpose, about the year 1765, during the administration of Mr Grenville, he presented a memorial to that minister, in which he requested the grant of a piece of ground in the Mews, for the site of an anatomical theatre. Dr Hunter undertook to expend L. 7000 on the building, and to endow a professorship of anatomy in perpetuity. This scheme did not meet with the reception it deserved. In a conversation on this subject soon afterwards with the earl of Shelburne, his lordship expressed a wish that the plan might be carried into execution by subscription, and very generously requested to have his name set down for a thousand guineas. Dr Hunter's delicacy would not allow him to adopt this proposal. He chose rather to execute it at his own expence; and accordingly purchased a spot of ground in Great Windmill-street, where he erected a spacious house, to which he removed from Jermyn-street in 1770. In this building, besides a handsome amphitheatre and other convenient apartments for his lectures and dissections, there was one magnificent room, fitted up with great elegance and propriety as a museum. Of the magnitude and value of his anatomical collection some idea

Hunter.

Hunter,
Hunting.

may be formed, when we consider the great length of years he employed in the making of anatomical preparations and in the dissection of morbid bodies, added to the eagerness with which he procured additions from the collections of Sandys, Hewson, Falconer, Blackall, and others, that were at different times offered for sale in this metropolis. His specimens of rare diseases were likewise frequently increased by presents from his medical friends and pupils; who, when any thing of this sort occurred to them, very justly thought they could not dispose of it more properly than by placing it in Dr Hunter's museum. Speaking of an acquisition in this way in one of his publications, he says, "I look upon every thing of this kind which is given to me, as a present to the public; and consider myself as thereby called upon to serve the public with more diligence."

Before his removal to Windmill-street, he had confined his collection chiefly to specimens of human and comparative anatomy and of diseases; but now he extended his views to fossils, and likewise to the promotion of polite literature and erudition. In a short space of time he became possessed of "the most magnificent treasure of Greek and Latin books that has been accumulated by any person now living since the days of Mead." A cabinet of ancient medals contributed likewise much to the richness of his museum. A description of part of the coins in this collection, struck by the Greek free cities, has lately been published by the Doctor's learned friend Mr Combe. In a classical dedication of this elegant volume to the queen, Dr Hunter acknowledges his obligations to her majesty. In the preface some account is given of the progress of the collection, which has been brought together since the year 1770, with singular taste, and at the expence of upwards of L. 20,000. In 1781, the museum received a valuable addition of shells, corals, and other curious subjects of natural history, which had been collected by the late worthy Dr Fothergill, who gave directions by his will, that his collection should be appraised after his death, and that Dr Hunter should have the refusal of it at L. 500 under the valuation. This was accordingly done, and Dr Hunter purchased it for the sum of L. 1200. The fame of this museum spread throughout Europe. Few foreigners distinguished for their rank or learning visited this metropolis without requesting to see it. Men of science of our own country always had easy access to it.—Considered in a collective point of view, it is perhaps without a rival.

Dr Hunter, at the head of his profession, honoured with the esteem of his sovereign, and in possession of every thing that his reputation and wealth could confer, seemed now to have attained the summit of his wishes. But these sources of gratification were imbibed by a disposition to the gout, which harassed him frequently during the latter part of his life, notwithstanding his very abstemious manner of living. On Saturday the 15th of March 1783, after having for several days experienced a return of a wandering gout, he complained of great head-ach and nausea. In this state he went to bed, and for several days felt more pain than usual both in his stomach and limbs. On the Thursday following he found himself so much recovered, that he determined to give the introductory lecture to the

operations of surgery. It was to no purpose that his friends urged to him the impropriety of such an attempt. He was determined to make the experiment, and accordingly delivered the lecture; but towards the conclusion his strength was so exhausted that he fainted away, and was obliged to be carried to bed by two servants. The following night and day his symptoms were such as indicated danger; and on Saturday morning Mr Combe, who made him an early visit, was alarmed on being told by Dr Hunter himself that during the night he had certainly had a paralytic stroke. As neither his speech nor his pulse were affected, and he was able to raise himself in bed, Mr Combe encouraged him to hope that he was mistaken. But the event proved the Doctor's idea of his complaint to be but too well founded; for from that time till his death, which happened on Sunday the 30th of March, he voided no urine without the assistance of the catheter, which was occasionally introduced by his brother; and purgative medicines were administered repeatedly without procuring a passage by stool. These circumstances, and the absence of pain, seemed to show, that the intestines and urinary bladder had lost their sensibility and power of contraction; and it was reasonable to presume that a partial palsy had affected the nerves distributed to those parts.

By his will, the use of his museum, under the direction of trustees, devolves to his nephew Matthew Baillie, B. A. and in case of his death to Mr Cruikshank for the term of thirty years, at the end of which period the whole collection is bequeathed to the university of Glasgow. The sum of eight thousand pounds sterling is left as a fund for the support and augmentation of the collection.

Dr Hunter was regularly shaped, but of a slender make, and rather below a middle stature. His manner of living was extremely simple and frugal, and the quantity of his food was small as well as plain. He was an early riser; and when business was over, was constantly engaged in his anatomical pursuits, or in his museum. There was something very engaging in his manner and address; and he had such an appearance of attention to his patients, when he was making his inquiries, as could hardly fail to conciliate their confidence and esteem. In consultation with his medical brethren, he delivered his opinions with diffidence and candour. In familiar conversation he was cheerful and unassuming. As a teacher of anatomy he has been long and deservedly celebrated. He was a good orator; and having a clear and accurate conception of what he taught, he knew how to place in distinct and intelligible points of view the most abstruse subjects of anatomy and physiology. Among other methods of explaining and illustrating his doctrines, he used frequently to introduce some apposite story or case that had occurred to him in his practice; and few men had acquired a more interesting fund of anecdotes of this kind, or related them in a more agreeable manner.

HUNTING, the exercise or diversion of pursuing four-footed beasts of game. See the article GAME.

Four-footed beasts are hunted in the fields, woods, and thickets, and that both with guns and greyhounds.

Birds, on the contrary, are either shot in the air,

Hunting. or taken with nets and other devices, which exercise is called *fowling*; or they are pursued and taken by birds of prey, which is called *hawking*. See the articles FOWLING, HAWKING, FALCONRY, SHOOTING, BIRD-Catching, and DECOY.

F. de Launay, professor of the French laws, has an express treatise of hunting. From those words of God to Adam, Gen. i. 26, and 28. and to Noah, Gen. ix. 2, 3. hunting was considered as a right devolved or made over to man; and the following ages appear to have been of the same sentiment. Accordingly we find, that among the more civilized nations it made one of their diversions; and as to the wilder and more barbarous, it served them with food and necessities. The Roman jurisprudence, which was formed on the manners of the first ages, made a law of it, and established it as a maxim, that as the natural right of things which have no master belongs to the first possessor, wild beasts, birds, and fishes, are the property of whomsoever can take them first.

But the northern nations of barbarians who over-ran the Roman empire, bringing with them a stronger taste for the diversion, and the people being now possessed of other and more easy means of subsistence from the lands and possessions of those they had vanquished, their chiefs and leaders began to appropriate the right of hunting, and, instead of a natural right, to make it a royal one. Thus it continues to this day; the right of hunting, among us, belonging only to the king, and those who derive it from him.

The hunting used by the ancients was much like that now practised for the rein-deer; which is seldom hunted at force, or with hounds; but only drawn with a blood-hound, and forestalled with nets and engines. Thus did they with all beasts; whence a dog is never commended by them for opening before he has discovered where the beast lies. Hence, they were not in any manner curious as to the music of their hounds, or the composition of their kennel or pack, either for deepness, loudness, or sweetness of cry, which is a principal point in the hunting of our days. Their huntsmen, indeed, were accustomed to shout and make a great noise, as Virgil observes in the third of his *Georgics*: *Ingentem clamore preme ad retia cervum*; But that confusion was only to bring the deer to the nets laid for him.

The Sicilian way of hunting had something in it very extraordinary.—The nobles or gentry being informed which way a herd of deer passed, gave notice to one another, and appointed a meeting; every one bringing with him a cross-bow or long-bow, and a bundle of staves shod with iron, the heads bored, with a cord passing through them all: thus provided, they came to the herd, and, casting themselves about in a large ring, surrounded the deer.—Then, each taking his stand, unbound his faggot, set up his stake, and tied the end of the cord to that of his next neighbour, at the distance of ten feet from one another.—Then taking feathers, dyed in crimson, and fastened on a thread, they tied them to the cord; so that with the least breath of wind they would whirl round.—

Which done, the persons who kept the stands withdrew, and hid themselves in the next covert. Then the chief ranger entering within the line with hounds to draw after the herd, roused the game with their cry; which flying towards the line, were turned off, and, still gazing on the shaking and shining feathers, wandered about as if kept in with a real wall or pale. The ranger still pursued, and calling every person by name as he passed by their stand, commanded him to shoot the first, third, or sixth, as he pleased: and if any of them missed, or singled out another than that assigned him, it was counted a grievous disgrace. By such means, as they passed by the several stations, the whole herd was killed by the several hands. *Pier. Hieroglyphic. lib. vii. cap. 6.*

Hunting formed the greatest part of the employment of the ancient Germans, and probably of the Britons also, when they were not engaged in war. We are informed by some ancient historians, that this was the case even as late as the third century with the unconquered Britons who lived beyond Adrian's wall; nay, that they subsisted chiefly by the prey they took in this way. The great attachment shown by all the Celtic nations to hunting, however, proceeded most probably from its being a kind of apprenticeship to war. Thus their youth acquired that courage, strength, swiftness, and dexterity in handling their arms, which made them so formidable in time of war to their enemies. Thus also they freed the country from many mischievous animals which abounded in the forests, furnishing themselves also with materials for those feasts which seem to have constituted their greatest pleasure. The young chieftains had thus likewise an opportunity of paying court to their mistresses, by displaying their bravery and agility, and making them presents of their game; nay, so strong and universal was the passion for hunting among the ancient Britons, that young ladies of the highest quality and greatest beauty spent much of their time in the chase. They employed much the same weapons in hunting that they did in war, viz. long spears, javelins, and bows and arrows; having also great numbers of dogs to assist them in finding and pursuing their game. These dogs, we are also told, were much admired among other nations, on account of their swiftness, strength, fierceness, and exquisite sense of smelling. They were of several different kinds, called by different names, and formed a considerable article of commerce. They were highly valued by all the Celtic nations, insomuch that some very comical penalties were inflicted upon those who were convicted of stealing them (A). From the poems of Ossian also it appears, that the Britons were not unacquainted with the art of catching birds with hawks trained for that purpose; but they seem to have been absolutely ignorant of the method of catching fish; for there is not a single allusion to this art in all the works of that venerable bard. Their ignorance of this art is both confirmed and accounted for by Dio Niceus, who assures us, that the ancient Britons never tasted fish, though they had innumerable multitudes in their seas, rivers, and lakes. "By the by (says Dr Henry), we may

(A) Si quis canem veltraum aut segutium vel petrunculum, præsumserit involare, jubemus ut convectus, coram omni populo, posteriora ipsius osculetur.

Hunting. may observe that this agreement between the poems of Ossian and the Greek historian, in a circumstance so singular, is at once a proof of the genuine antiquity of these poems, and that the Greek and Roman writers were not so ill informed about the affairs and manners of the ancient Britons as some have imagined."

The Mexicans, whatever imbecility may be imputed to them in other respects, were very dexterous in hunting. They used bows and arrows, darts, nets, snares, and a kind of tubes named *carbottane*, through which they shot by blowing out little balls at birds. Those which the kings and great men made use of were curiously carved and painted, and likewise adorned with gold and silver. Besides the exercise of the chase which private individuals took either for amusement or to provide food for themselves, there were general hunting-matches, sometimes appointed by the king; at others, undertaken with a view to provide plenty of victims for sacrifices. A large wood, generally that of Zacatapec, not far distant from the capital, was pitched upon as the scene of these grand hunting-matches. Here they chose the place best adapted for setting a great number of snares and nets. The wood was inclosed by some thousands of hunters, forming a circle of six, seven, or eight miles, according to the number of animals they intended to take. Fire was then set to the grass in a great number of places, and a terrible noise made with drums, horns, shouting, and whistling. The hunters gradually contracted their circle, continuing the noise till the game were inclosed in a very small space. They were then killed or taken in snares, or with the hands of the hunters. The number of animals taken or destroyed on these occasions was so great, that the first Spanish viceroy of Mexico would not believe it without making the experiment himself. The place chosen for his hunting-match was a great plain in the country of the Otomies, lying between the villages of Xilotepec and S. Giovanni del Rio; the Indians being ordered to proceed according to their usual customs in the times of their paganism. The viceroy, attended by a vast retinue of Spaniards, repaired to the place appointed, where accommodations were prepared for them in houses of wood erected for the purpose. A circle of more than 15 miles was formed by 11,000 Otomies, who started such a quantity of game on the plain, that the viceroy was quite astonished, and commanded the greater part of them to be set at liberty, which was accordingly done. The number retained, however, was still incredibly great, were it not attested by a witness of the highest credit. On this occasion upwards of 600 deer and wild goats, 100 cajotes, with a surprising number of hares, rabbits, and other smaller animals. The plain still retains the Spanish name *Cazadero*, which signifies the "place of the chase."

The Mexicans, besides the usual methods of the chase, had particular contrivances for catching certain animals. Thus, to catch young asses, they made a small fire in the woods, putting among the burning coals a particular kind of stone named *cacalotl* "raven or black stone," which bursts with a loud noise when heated. The fire was covered with earth, and a little maize laid around it. The asses quickly assembled with their young, in order to feed upon the maize; but while they were thus employed, the stone burst, and

scared away the old ones by the explosion, while the young ones, unable to fly, were carried off by the hunters. Serpents were taken even by the hands, seizing them intrepidly by the neck with one hand, and sewing up their mouths with the other. This method is still practised. They showed the greatest dexterity in tracing the steps of wild beasts, even when an European could not have discerned the smallest print of their feet. The Indian method, however, was by observing sometimes the herbs or leaves broken down by their feet; sometimes the drops of blood which fell from them when wounded. It is said that some of the American Indians show still greater dexterity in discovering the tracks of their enemies, which to an European would be altogether imperceptible.

Hunting was a favourite diversion of the great and bloody conqueror Jenghiz Khan, if indeed we can apply the word *diversion* to a monster whose mind was set upon the destruction of his own species, and who only endeavoured to make the murder of brutes subservient to that of men, by keeping his soldiers in a kind of warfare with the beasts when they had no human enemies to contend with. His expeditions were conducted on a plan similar to that of the Mexicans already mentioned; and were no doubt attended with still greater success, as his numerous army could inclose a much greater space than all the Indians whom the Spanish viceroy could muster. The East Indian princes still show the same inclination to the chase; and Mr Blane, who attended the hunting excursions of Asoph Ul Dowlah visir of the Mogul empire and nabob of Oude in 1785 and 1786, gives the following account of the method practised on this occasion.

The time chosen for the hunting party is about the beginning of December; and the diversion is continued till the heats, which commence about the beginning of March, oblige them to stop. During this time a circuit of between 400 and 600 miles is generally made; the hunters bending their course towards the skirts of the northern mountains, where the country is wild and uncultivated. The visir takes along with him not only his court and seraglio, but a great part of the inhabitants of his capital. His immediate attendants may amount to about 2000; but besides these he is also followed by 500 or 600 horse, and several battalions of regular sepoy with their field pieces. Four or five hundred elephants are also carried along with him; of which some are used for riding, others for fighting, and some for clearing the jungles and forests of the game. About as many sumpter horses of the beautiful Persian and Arabian breeds are carried along with him. A great many wheel carriages drawn by bullocks likewise attend, which are used chiefly for the convenience of the women; sometimes also he has an English chaise or two, and sometimes a chariot; but all these as well as the horses are merely for show, the visir himself never using any other conveyance than an elephant, or sometimes when fatigued or indisposed a palanquin. The animals used in the sport are principally greyhounds, of which there may be about 300; he has also about 200 hawks, and a few trained leopards for hunting deer. There are a great number of marksmen, whose profession it is to shoot deer; with many fowlers, who provide game; as none of the natives of India know how to shoot game with small

Hunting. small shot, or to hunt with slow hounds. A vast number of matchlocks are carried along with the company with many English pieces of various kinds, 40 or 50 pairs of pistols, bows and arrows, besides swords, daggers, and sabres without number. There are also nets of various kinds, some for quail, and others very large, for fishing, which are carried along with him upon elephants, attended by fishermen, so as always to be ready for throwing into any river or lake that may be met with. Every article that can contribute to luxury or pleasure is likewise carried along with the army. A great many carts are loaded with the Ganges water, and even ice is transported for cooling the drink. The fruits of the season and fresh vegetables are daily sent to him from his gardens by bearers stationed at the distance of every ten miles; by which means each article is conveyed day or night at the rate of four miles an hour. Besides the animals already mentioned, there are also fighting antelopes, buffaloes, and rams in great numbers; also several hundred pigeons, some fighting cocks, with a vast variety of parrots, nightingales, &c.

To complete the magnificence or extravagance of this expedition, there is always a large bazar, or moving town, which attends the camp; consisting of shopkeepers and artificers of all kinds, money-changers, dancing-women; so that, on the most moderate calculation, the whole number of people in his camp cannot be computed at fewer than 20,000. The nabob himself, and all the gentlemen of his camp, are provided with double sets of tents and equipage, which are always sent on the day before to the place to which he intends to go; and this is generally eight or ten miles in whatever direction most game is expected; so that by the time he has finished his sport in the morning, he finds his whole camp ready pitched for his reception.

The nabob, with the attending gentlemen, proceed in a regular moving court or durbar, and thus they keep conversing together and looking out for game. A great many foxes, hares, jackals, and sometimes deer, are picked up by the dogs as they pass along: the hawks are carried immediately before the elephants, and let fly at whatever game is sprung for them, which is generally partridges, bustards, quails, and different kinds of herons; these last affording excellent sport with the falcons or sharp-winged hawks. Wild boars are sometimes started, and either shot or run down by the dogs and horsemen. Hunting the tyger, however, is looked upon as the principal diversion, and the discovery of one of these animals is accounted a matter of great joy. The cover in which the tyger is found is commonly long grass, or reeds of such an height as frequently to reach above the elephants; and it is difficult to find him in such a place, as he commonly endeavours either to steal off, or lies so close to the ground that he cannot be roused till the elephants are almost upon him. He then roars and skulks away, but is shot at as soon as he can be seen; it being generally contrived that the nabob shall have the compliment of firing first. If he be not disabled, the tyger continues to skulk along, followed by the line of elephants; the nabob and others shooting at him as often as he can be seen till he falls. The elephants themselves are very much afraid of this terrible animal, and discover their apprehensions by shrieking and roaring

as soon as they begin to smell him or hear him growl; generally attempting to turn away from the place where he is. When the tyger can be traced to a particular spot, the elephants are disposed of in a circle round him; in which case he will at last make a desperate attack, springing upon the elephant that is nearest, and attempting to tear him with his teeth or claws. Some, but very few, of the elephants, can be brought to attack the tyger; and this they do by curling up their trunks under their mouths, and then attempting to toss, or otherwise destroy him with their tusks, or to crush him with their feet or knees. It is considered as good sport to kill one tyger in a day; though sometimes, when a female is met with her young ones, two or three will be killed.

The other objects of pursuit in these excursions are wild elephants, buffaloes, and rhinoceroses. Our author was present at the hunting of a wild elephant of vast size and strength. An attempt was first made to take him alive by surrounding him with tame elephants, while he was kept at bay by crackers and other fire-works; but he constantly eluded every effort of this kind. Sometimes the drivers of the tame elephants got so near him, that they threw strong ropes over his head, and endeavoured to detain him by fastening them around trees; but he constantly snapped the ropes like pack-threads, and pursued his way to the forest. Some of the strongest and most furious of the fighting elephants were then brought up to engage him; but he attacked them with such fury that they were all obliged to desist. In his struggle with one of them he broke one of his tusks, and the broken piece, which was upwards of two inches in diameter, of solid ivory, flew up into the air several yards above their heads. Orders were now given to kill him, as it appeared impossible to take him alive; but even this was not accomplished without the greatest difficulty. He twice turned and attacked the party who pursued him; and in one of these attacks struck the elephant obliquely on which the prince rode, threw him upon his side, but then passed on without offering farther injury. At last he fell dead, after having received as was supposed upwards of 1000 balls into his body.

Notwithstanding the general passion among most nations for hunting, however, it has by many been deemed an exercise inconsistent with the principles of humanity. The late king of Prussia expressed himself on this subject in the following manner. "The chase is one of the most sensual of pleasures, by which the powers of the body are strongly exerted, but those of the mind remain unemployed. It is an exercise which makes the limbs strong, active, and pliable; but leaves the head without improvement. It consists in a violent desire in the pursuit, and the indulgence of a cruel pleasure in the death, of the game. I am convinced, that man is more cruel and savage than any beast of prey: We exercise the dominion given us over these our fellow-creatures in the most tyrannical manner. If we pretend to any superiority over the beasts, it ought certainly to consist in reason; but we commonly find that the most passionate lovers of the chase renounce this privilege, and converse only with their dogs, horses, and other irrational animals. This renders them wild and unfeeling; and it is probable that they cannot be very merciful to the human species.

Hunting.

Hunting.

For a man who can in cold blood torture a poor innocent animal, cannot feel much compassion for the distresses of his own species. And, besides, can the chase be a proper employment for a thinking mind?"

The arguments used by his majesty against hunting seem indeed to be much confirmed by considering the various nations who have most addicted themselves to it. These, as must be seen from what has already been said, were all barbarous; and it is remarkable, that Nimrod, the first great hunter of whom we have any account, was likewise the first who oppressed and enslaved his own species. As nations advanced in civilization, it always became necessary to restrain by law the inclination of the people for hunting. This was done by the wise legislator Solon, lest the Athenians should neglect the mechanic arts on its account. The Lacedemonians, on the contrary, indulged themselves in this diversion without controul; but they were barbarians, and most cruelly oppressed those whom they had in their power, as is evident from their treatment of the Helots. The like may be said of the Egyptians, Persians, and Scythians; all of whom delighted in war, and oppressed their own species. The Romans, on the other hand, who were somewhat more civilized, were less addicted to hunting. Even they, however, were exceedingly barbarous, and found it necessary to make death and slaughter familiar to their citizens from their infancy. Hence their diversions of the amphitheatre and circus, where the hunting of wild beasts was shown in the most magnificent and cruel manner; not to mention their still more cruel sports of gladiators, &c.

In two cases only does it seem possible to reconcile the practice of hunting with humanity; viz. either when an uncultivated country is over-run with noxious animals; or when it is necessary to kill wild animals for food. In the former case, the noxious animals are killed because they themselves would do so if they were allowed to live; but if we kill even a lion or a tyger merely for the pleasure of killing him, we are undoubtedly chargeable with cruelty. In like manner, our modern fox-hunters expressly kill foxes, not in order to destroy the breed of these noxious animals, but for the pleasure of seeing them exert all their power and cunning to save their lives, and then beholding them torn in pieces after being half dead with fatigue. This refinement in cruelty, it seems, is their favourite diversion; and it is accounted a crime for any person to destroy these animals in self-defence, as appears from the following passage in Mr Beckford's treatise on hunting. "Besides the digging of foxes, by which method many young ones are taken and old ones destroyed, traps, &c. are too often fatal to them. Farmers for their lambs (which, by the bye, few foxes ever kill), gentlemen for their game, and old women for their poultry, are their inveterate enemies. In the country where I live, most of the gentlemen are sportsmen; and even those who are not, show every kind of attention to those who are. I am sorry it is otherwise with you; and that your old gouty neighbour should destroy your foxes, I must own concerns me. I know some gentlemen, who, when a neighbour had destroyed all their foxes, and thereby prevented them from pursuing a favourite amusement, loaded a cart with spaniels, and went all together and destroyed his pheasants. I think they might have called this very pro-

perly *lex talionis*: and it had the desired effect; for as the gentleman did not think it prudent to fight them all, he took the wiser method, he made peace with them. He gave an order that no more foxes should be destroyed, and they never afterwards killed any of his pheasants."

Hunting.

In the first volume of the Manchester Transactions we have a dissertation upon the diversions of hunting, shooting, &c. as compatible with the principles of humanity. One argument used by the author is, that death is no positive evil to brutes. "It would perhaps (says he) be too hasty an assertion to affirm, that death to brutes is no evil. We are not competent to determine whether their existence, like our own, may not extend to some future mode of being, or whether the present limited sphere is all in which they are interested. On so speculative a question little can be advanced with precision; nor is it necessary for the investigation of the subject before us. If we may be allowed to reason from what we know, it may be safely conjectured, that death to brutes is no positive evil: we have no reason to believe they are endowed with foresight; and therefore, even admitting that with them the pleasures of life exceed its pains and cares, in terminating their existence, they only suffer a privation of pleasure."

On this extraordinary piece of reasoning we may observe, that it would hold much more against the human species than against the brutes. There are few amongst us willing to allow that the pleasures we enjoy are equivalent to our pains and cares: death therefore must be to us a relief from pain and misery, while to the brutes it is a privation of pleasure. Hence, if it be no positive evil for a brute to suffer death, to a man it must be a positive good: add to which, that a man lives in hope of an endless and glorious life, while a brute has no such hope; so that, if to kill a brute, on our author's principles be no cruelty, to kill a man must be an act of tenderness and mercy!

Another argument, no less inconclusive, is our author's supposing that death from disease is much more to be dreaded in a brute than a violent death. Were brutes naturally in as helpless a state as man, no doubt their want of support from society in cases where they are attacked by sickness, would be very deplorable; but it must be considered that the parallel betwixt the two species is in this respect by no means fair. A brute has every where its food at hand, and is naturally capable of resisting the inclemencies of the weather; but man has not only a natural inability to procure food for himself in the way that the brutes do, but is, besides, very tender and incapable of resisting the inclemency of the air. Hence, a man unassisted by society must very soon perish; and, no doubt, it would be much more merciful for people to kill one another at once, than to deprive them of the benefits of society, as is too frequently done in various ways needless to be mentioned at present. A brute, however, has nothing to fear. As long as its stomach can receive food, nature offers an abundant supply. One that feeds upon grass has it always within reach; and a carnivorous one will content itself with worms or insects, which, as long as it is able to crawl it can still make a shift to provide; but so totally helpless is man when left to himself in a state of weakness, that many
barbarous

Hunting. barbarous nations have looked upon the killing of their old and infirm people to be an act of mercy.

Equally unhappy is our author in his other arguments, that the quick transition from a state of perfect health to death mitigates the severity. The transition is not quick. The sportsmen estimate their diversion by the length of the chase; and during all that time the creature must be under the strongest agonies of terror; and what person of humanity is there who must not feel for an animal in this situation? All this is assented to by our author, who says, "Hard is the heart who does not commiserate the sufferer." Is not this an acknowledgment on his part, that before a person can become a thorough sportsman, he must harden his heart, and stifle those amiable sensations of compassion, which on all occasions ought to be encouraged towards every creature, unless in cases of necessity. But in the present case no necessity is or can be pretended. If a gentleman chooses to regale himself with venison of any kind, he may breed the animals for the purpose. We call Domitian cruel, because he took pleasure in catching flies, and stabbing them with a bodkin. A butcher is excluded from sitting on a jury on account of his being accustomed to fights which are deemed inhuman; but whether it is more inhuman to knock down an ox at once with an ax, or to tear him in pieces with dogs (for they would accomplish the purpose if properly trained), must be left to the sportsmen to determine.

Lastly, the great argument in favour of hunting, that it contributes to the health of the body and exhilaration of the spirits, seems equally fallacious with the rest. It cannot be proved that hunters are more healthy or long lived than other people. That exercise will contribute to the preservation of health, as well as to the exhilaration of the mind, is undoubted; but many other kinds of exercise will do this as well as hunting. A man may ride from morning to night, and amuse himself with viewing and making remarks on the country through which he passes; and surely there is no person will say that this exercise will tend to impair his health or sink his spirits. A man may amuse and exercise himself not only with pleasure, but profit also, in many different ways, and yet not accustom himself to behold the death of animals with indifference. It is this that constitutes the cruelty of hunting; because we thus wilfully extinguish in part that principle naturally implanted in our nature, which if totally eradicated would set us not only on a level with the most ferocious wild beasts, but perhaps considerably below them; and it must always be remembered, that whatever pleasure terminates in death is cruel, let us use as many palliatives as we please to hide that cruelty from the eyes of others, or even from our own.

The gentlemen and masters of the sport have invented a set of terms which may be called the *hunting-language*. The principal are those which follow:

1. For beasts as they are in company.—They say, a *herd* of harts, and all manner of deer. A *bay* of roes. A *sounder* of swine. A *route* of wolves. A *riches* of martens. A *brace* or *leash* of bucks, foxes, or hares. A *couple* of rabbits or coney.

2. For their lodging.—A hart is said to *harbour*.

A buck *lodges*. A roe *beds*. A hare *seats* or *forms*. A coney *sits*. A fox *kennels*. A marten *trees*. An otter *watches*. A badger *earths*. A boar *couches*.—Hence, to express their dislodging, they say, *Unharbour* the hart. *Rouse* the buck. *Start* the hare. *Bolt* the coney. *Unkennel* the fox. *Untree* the marten. *Vent* the otter. *Dig* the badger. *Rear* the boar.

3. For their noise at rutting time.—A hart *belletb*. A buck *growns* or *troats*. A roe *bellows*. A hare *beats* or *taps*. An otter *whines*. A boar *freams*. A fox *barks*. A badger *shricks*. A wolf *howls*. A goat *rattles*.

4. For their copulation.—A hart or buck goes to *rut*. A roe goes to *tourn*. A boar goes to *brim*. A hare or coney goes to *buck*. A fox goes to *clickitting*. A wolf goes to *match* or *make*. An otter *hunteth* for his kind.

5. For the footing and treading.—Of a hart, we say the *slot*. Of a buck, and all fallow-deer, the *view*. Of all deer, if on the grass and scarce visible, the *foiling*. Of a fox, the *print*; and of other the like vermin, the *footing*. Of an otter, the *marks*. Of a boar, the *track*. The hare, when in open field, is said to *fore*; when she winds about to deceive the hounds, she *doubles*; when she beats on the hard highway, and her footing comes to be perceived, she *pricketh*: in snow, it is called the *trace* of the hare.

6. The tail of a hart, buck, or other deer, is called the *single*. That of a boar, the *wreath*. Of a fox, the *brush* or *drag*; and the tip at the end, the *chape*. Of a wolf, the *stern*. Of a hare and coney, the *scut*.

7. The ordure or excrement of a hart and all deer, is called *sewmeets* or *sewmishng*. Of a hare, *crotils* or *crotifng*. Of a boar, *lesses*. Of a fox, the *billiting*; and of other the like vermin, the *fuants*. Of an otter, the *spraints*.

8. As to the attire of deer, or parts thereof, those of a stag, if perfect, are the *bur*, the *pearls*, the little *knots* on it, the *beam*, the *gutters*, the *antler*, the *sur-antler*, *royal*, *sur-royal*, and all at top the *croches*. Of the buck, the *bur*, *beam*, *brow-antler*, *black-antler*, *advancer*, *palm*, and *spellers*. If the croches grow in the form of a man's hand, it is called a *palmed head*. Heads bearing not above three or four, and the croches placed aloft, all of one height, are called *crowned heads*. Heads having double croches, are called *forked heads*, because the croches are planted on the top of the beam like forks.

9. They say, a *litter* of cubs, a *nest* of rabbits, a squirrel's *dray*.

10. The terms used in respect of the dogs, &c. are as follow.—Of gre-hounds, two make a *brace*; of hounds, a *couple*. Of gre-hounds, three make a *leash*; of hounds, a *couple* and *half*.—They say, *let slip* a gre-hound; and, *cast off* a hound. The string wherein a gre-hound is led, is called a *leash*; and that of a hound, a *lyome*. The gre-hound has his *collar*, and the hound his *couples*. We say a *kennel* of hounds, and a *pack* of beagles.

HUNTING, as practised among us, is chiefly performed with dogs; of which we have various kinds, accommodated to the various kinds of game, as *hounds*, *gre-hounds*, *blood-hounds*, *terriers*, &c. See CANIS, HOUND, &c.

Hunting.

In the kennels or packs they generally rank them under the heads of *enterers, drivers, flyers, tyers, &c.*

On some occasions, nets, spears, and instruments for digging the ground, are also required: nor is the hunting-horn to be omitted.

The usual chases among us are, the *hart, buck, roe, hare, fox, badger, and otter*.—We shall here give something of what relates to each thereof: first premising an explanation of some general terms and phrases, more immediately used in the progress of the sport itself; what belongs to the several sorts of game in particular being reserved for the respective articles.

When the hounds, then, being cast off, and finding the scent of some game, begin to open and cry; they are said to *challenge*. When they are too busy ere the scent be good, they are said to *babble*. When too busy where the scent is good, to *barwl*. When they run it endwise orderly, holding in together merrily, and making it good, they are said to be in *full cry*. When they run along without opening at all, it is called *running mute*.

When spaniels open in the string, or a gre-hound in the course, they are said to *lapse*.

When beagles bark and cry at their prey, they are said to *yearn*.

When the dogs hit the scent the contrary way, they are said to *draw amiss*.

When they take fresh scent, and quit the former chase for a new one, it is called *hunting change*.

When they *hunt* the game by the heel or track, they are said to *hunt counter*.

When the chase goes off, and returns again, traversing the same ground, it is called *hunting the foil*.

When the dogs run at a whole herd of deer, instead of a single one, it is called *running riot*.

Dogs set in readiness where the game is expected to come by, and cast off after the other hounds are passed, are called a *relay*. If they be cast off ere the other dogs be come up, it is called *vauntlay*.

When, finding where the chase has been, they make a proffer to enter, but return, it is called a *blemish*.

A lesson on the horn to encourage the hounds, is named a *call*, or a *recheat*. That blown at the death of a deer, is called the *mort*. The part belonging to the dogs of any chase they have killed, is the *reward*. They say, *take off* a deer's skin; *strip* or *case* a hare, fox, and all sorts of vermin; which is done by beginning at the snout, and turning the skin over the ears down to the tail.

HUNTING is practised in a different manner, and with different apparatus, according to the nature of the beasts which are hunted, a description of whom may be found under their respective articles, *infra*.

With regard to the seasons, that for hart and buck-hunting begins a fortnight after midsummer, and lasts till Holy-rood day; that for the hind and doe, begins on Holy-rood day, and lasts till Candlemas; that for fox-hunting begins at Christmas, and holds till Lady-day; that for roe hunting begins at Michaelmas, and ends at Christmas; hare-hunting commences at Michaelmas, and lasts till the end of February; and where the wolf and bore are hunted, the season for each begins at Christmas, the first ending at Lady-day, and the latter at the Purification.

When the sportsmen have provided themselves with

nets, spears, and a hunting-horn to call the dogs together, and likewise with instruments for digging the ground, the following directions will be of use to them in the pursuit of each sort of game.

Badger-HUNTING. In doing this, you must seek the earths and burrows where he lies, and in a clear moonshine night go and stop all the burrows, except one or two, and therein place some sacks, fastened with drawing strings, which may shut him in as soon as he straineth the bag. Some use no more than to set a hoop in the mouth of the sack, and so put it into the hole; and as soon as the badger is in the sack and straineth it, the sack slippeth off the hoop and follows him to the earth, so he lies tumbling therein till he is taken. These sacks or bags being thus set, cast off the hounds, beating about all the woods, coppices, hedges, and tufts, round about, for the compass of a mile or two; and what badgers are abroad, being alarmed by the hounds, will soon betake themselves to their burrows; and, observe that he who is placed to watch the sacks, must stand close and upon a clear wind; otherwise the badger will discover him, and will immediately fly some other way into his burrow. But if the hounds can encounter him before he can take his sanctuary, he will then stand at a bay like a boar, and make good sport, grievously biting and clawing the dogs, for the manner of their fighting is lying on their backs, using both teeth and nails; and by blowing up their skins defend themselves against all bites of the dogs, and blows of the men upon their noses. And for the better preservation of your dogs, it is good to put broad collars about their necks made of grey skins.

When the badger perceives the terriers to begin to yearn him in his burrow, he will stop the hole betwixt him and the terriers, and if they still continue baying, he will remove his couch into another chamber or part of the burrow, and so from one to another, barricading the way before them, as they retreat, until they can go no further. If you intend to dig the badger out of his burrow, you must be provided with the same tools as for digging out a fox; and besides, you should have a pail of water to refresh the terriers, when they come out of the earth to take breath and cool themselves. It will also be necessary to put collars of bells about the necks of your terriers, which making a noise may cause the badger to bolt out. The tools used for digging out of the badger, being troublesome to be carried on mens backs, may be brought in a cart. In digging, you must consider the situation of the ground, by which you may judge where the chief angles are; for else, instead of advancing the work, you will hinder it. In this order you may besiege them in their holds, or castles; and may break their platforms, parapets, casemets, and work to them with mines and countermines until you have overcome them.

Having taken a live and lusty badger, if you would make sport, carry him home in a sack and turn him out in your court-yard, or some other inclosed place, and there let him be hunted and worried to death by your hounds.

There are the following profits and advantages which accrue by killing this animal. Their flesh, blood, and grease, though they are not good food, yet are very useful for physicians and apothecaries for oils, ointments,

Hunting. ments, salves, and powders for shortness of breath, the cough of the lungs, for the stone, sprained sinews, colt-aches, &c. and the skin being well dressed, is very warm and good for old people who are troubled with paralytic distempers.

Boar-HUNTING. See BOAR.

Buck-HUNTING. Here the same hounds and methods are used as in running the stag; and, indeed, he that can hunt a hart or stag well, will not hunt a buck ill.

In order to facilitate the chase, the game-keeper commonly selects a fat buck out of the herd, which he shoots in order to maim him, and then he is run down by the hounds.

As to the method of hunting the buck. The company generally go out very early for the benefit of the morning. Sometimes they have a deer ready lodged; if not, the coverts are drawn till one is roused: or sometimes in a park a deer is pitched upon, and forced from the herd, then more hounds are laid on to run the chase. If you come to be at a fault, the old staunch hounds are only to be relied upon till you recover him again: if he be funk, and the hounds thrust him up, it is called an *imprime*, and the company all sound a recheat; when he is run down, every one strives to get in to prevent his being torn by the hounds, fallow deer seldom or never standing at bay.

He that first gets in, cries hoo-up, to give notice that he is down, and blows a death. When the company are all come in, they paunch him, and reward the hounds; and generally the chief person of quality amongst them *takes say*, that is, cuts his belly open, to see how fat he is. When this is done, every one has a chop at his neck; and the head being cut off, is shewed to the hounds, to encourage them to run only at male deer, which they see by the horns, and to teach them to bite only at the head: then the company all standing in a ring, one blows a single death; which being done, all blow a double recheat, and so conclude the chase with a general halloo of hoo-up, and depart the field to their several homes, or to the place of meeting; and the huntsman, or some other, hath the deer cast cross the buttocks of his horse, and so carries him home.

Fox-HUNTING makes a very pleasant exercise, and is either above or below ground.

I. *Above-ground.* To hunt a fox with hounds, you must draw about groves, thickets, and bushes near villages. When you find one, it will be necessary to stop up his earth the night before you design to hunt, and that about midnight; at which time he is gone out to prey: this may be done by laying two white sticks across in his way, which he will imagine to be some gin or trap laid for him; or else they may be stopped up with black thorns and earth mixed together.

Mr Beckford is of opinion that for fox-hunting the pack should consist of 25 couple. The hour most favourable for the diversion is an early one; and he thinks that the hounds should be at the cover at sun-rising. The huntsman should then throw in his hounds as quietly as he can, and let the two whippers-in keep wide of him on either hand; so that a single hound may not escape them; let them be attentive to his halloo, and let the sportsmen be ready to encourage or rate as that directs. The fox ought on no account

VOL. VIII. Part II.

Hunting. to be hallooed too soon, as in that case he would most certainly turn back again, and spoil all the sport.—Two things our author particularly recommends, viz. the making all the hounds steady, and making them all draw. “Many huntsmen (says he) are fond of having them at their horse’s heels; but they never can get so well or so soon together as when they spread the cover; besides, I have often known, when there have been only a few finders, that they have found their fox gone down the wind, and been heard of no more that day. Much depends upon the first finding of your fox; for I look upon a fox well found to be half killed. I think people are generally in too great a hurry on this occasion. There are but few instances where sportsmen are not too noisy, and too fond of encouraging their hounds, which seldom do their business so well as when little is said to them. The huntsman ought certainly to begin with his foremost hounds; and I should wish him to keep as close to them as he conveniently can; nor can any harm arise from it, unless he should not have common sense. No hounds can then slip down the wind and get out of his hearing; he will also see how far they carry the scent, a necessary requisite; for without it he never can make a cast with any certainty.—You will find it not less necessary for your huntsman to be active in pressing his hounds forward when the scent is good, than to be prudent in not hurrying them beyond it when it is bad. It is his business to be ready at all times to lend them that assistance which they so frequently need, and which when they are first at a fault is then most critical. A fox-hound at that time will exert himself most; he afterwards cools and becomes more indifferent about his game. Those huntsmen who do not get forward enough to take advantage of this eagerness and impetuosity, and direct it properly, seldom know enough of hunting to be of much use to them afterwards. Though a huntsman cannot be too fond of hunting, a whipper-in easily may. His business will seldom allow him to be forward enough with the hounds to see much of the sport. His only thought therefore should be to keep the hounds together, and to contribute as much as he can to the killing of the fox: keeping the hounds together is the surest means to make them steady. When left to themselves they seldom refuse any blood they can get; they become conceited; learn to tie upon the scent; and besides this they frequently get a trick of hunting by themselves, and are seldom good for much afterwards.

“Every country is soon known; and nine foxes out of ten, with the wind in the same quarter, will follow the same track. It is easy therefore for the whipper-in to cut short, and catch the hounds again. With a high scent you cannot push on hounds too much. Screams keep the fox forward, at the same time that they keep the hounds together, or let in the tail-hounds: they also enliven the sport; and, if discreetly used, are always of service; but in cover they should be given with the greatest caution. Halloos seldom do any hurt when you are running up the wind, for then none but the tail-hounds can hear you: when you are running down the wind, you should halloo no more than may be necessary to bring the tail-hounds forward; for a hound that knows his business seldom wants encouragement when he is upon a scent.—Most

4 Y

fox-

Hunting. fox-hunters wish to see their hounds run in a *good style*. I confess I myself am one of those; I hate to see a string of them; nor can I bear to see them creep where they can leap. A pack of harriers, if they have time, may kill a fox, but I defy them to kill him in the style in which he ought to be killed; they must hunt him down. If you intend to tire him out, you must expect to be tired also yourself; I never wish a chase to be less than one hour, or to exceed two: it is sufficiently long if properly followed: it will seldom be longer unless there be a fault somewhere; either in the day, the huntsman, or the hounds.

“Changing from the hunted fox to a fresh one is as bad an accident as can happen to a pack of fox-hounds, and requires all the ingenuity and observation that man is capable of to guard against it. Could a fox-hound distinguish a hunted fox as the deer-hound does the deer that is blown, fox-hunting would then be perfect. A huntsman should always listen to his hounds while they are running in cover; he should be particularly attentive to the headmost hounds, and he should be constantly on his guard against a skitter; for if there be two scents, he must be wrong. Generally speaking, the best scent is least likely to be that of the hunted fox: and as a fox seldom suffers hounds to run up to him as long as he is able to prevent it; so, nine times out of ten, when foxes are hallooed early in the day, they are all fresh foxes. The hounds most likely to be right are the hard running line-hunting ones; or such as the huntsman knows had the lead before there arose any doubt of changing. With regard to the fox, if he break over an open country, it is no sign that he is hard run; for they seldom at any time will do that unless they are a great way before the hounds. Also if he run up the wind;—they seldom or never do that when they have been long hunted and grow weak; and when they run their foil, that also may direct him. All this requires a good ear and nice observation; and indeed in that consists the chief excellence of a huntsman.

“When the hounds divide and are in two parts, the whipper-in, in stopping, must attend to the huntsman and wait for his halloo, before he attempts to stop either: for want of proper management in this respect I have known the hounds stopped at both places, and both foxes lost. If they have many scents, and it is quite uncertain which is the hunted fox, let him stop those that are farthest down the wind; as they can hear the others, and will reach them soonest: in such a case there will be little use in stopping those that are up the wind. When hounds are at a check, let every one be silent and stand still. Whippers-in are frequently at this time coming on with the tail hounds. They should never halloo to them when the hounds are at fault; the least thing does them harm at such a time, but a halloo more than any other. The huntsman, at a check, had better let his hounds alone; or content himself with holding them forward, without taking them off their noses.—Should they be at a fault, after having made their own cast (which the huntsman should always first encourage them to do), it is then his business to assist them further; but except in some particular instances, I never approve of their being cast as long as they are inclined to hunt. The first cast I bid my huntsman make is generally a regular one, not choosing to rely entirely on his judgment: if that should not succeed, he is then at liberty to follow his own opinion,

and proceed as observation or genius may direct. When such a cast is made, I like to see some mark of good sense and meaning in it; whether down the wind, or towards some likely cover or strong earth. However, as it is at best uncertain, I always wish to see a regular cast before I see a knowing one; which, as a last resource, should not be called forth till it be wanted: The letting hounds alone is but a negative goodness in a huntsman; whereas it is true this last shows real genius; and to be perfect, it must be born with him. There is a fault, however, which a knowing huntsman is too apt to commit: he will find a fresh fox, and then claim the merit of having recovered the hunted one. It is always dangerous to throw hounds into a cover to retrieve a lost scent; and unless they hit him in, is not to be depended on.

“Gentlemen, when hounds are at fault, are too apt themselves to prolong it. They should always stop their horses some distance behind the hounds; and if it be possible to remain silent, this is the time to be so. They should be careful not to ride before the hounds or over the scent; nor should they ever meet a hound in the face unless with a design to stop him. Should you at any time be before the hounds, turn your horse's head the way they are going, get out of their track, and let them pass by you. In dry weather, and particularly in heathy countries, foxes will run the roads. If gentlemen at such times will ride close upon the hounds, they may drive them miles without any scent.—High mettled fox-hounds are seldom inclined to stop whilst horses are close at their heels. No one should ever ride in a direction which if persisted in would carry him amongst the hounds, unless he be at a great distance behind them.

“The first moment that hounds are at fault is a critical one for the sport-people, who should then be very attentive. Those who look forward may perhaps see the fox; or the running of sheep, or the pursuit of crows, may give them some tidings of him. Those who listen may sometimes take a hint which way he is gone from the chattering of a magpie; or perhaps be at a certainty from a distant halloo: nothing that can give any intelligence at such a time ought to be neglected. Gentlemen are too apt to ride all together: were they to spread more, they might sometimes be of service; particularly those who, from a knowledge of the sport, keep down the wind: it would then be difficult for either hounds or fox to escape their observation.—You should, however, be cautious how you go to a halloo. The halloo itself must in a great measure direct you; and though it afford no certain rule, yet you may frequently guess whether it can be depended upon or not. At the sowing-time, when boys are keeping off the birds, you will sometimes be deceived by their halloo; so that it is best, when you are in doubt, to send a whipper-in to know the certainty of the matter.”

Hounds ought not to be cast as long as they are able to hunt. It is a common, though not a very just idea, that a hunted fox never stops; but our author informs us that he has known them stop even in wheel-ruts in the middle of a down, and get up in the middle of the hounds. The greatest danger of losing a fox is at the first finding him, and when he is sinking; at both which times he frequently will run short, and the eagerness of the hounds will frequently carry them beyond the scent. When a fox is first found, every one ought

Hunting. ought to keep behind the hounds till they are well settled to the scent; and when the hounds are catching him, our author wishes them to be as silent as possible; and likewise to eat him eagerly after he is caught. In some places they have a method of *treeing* him; that is, throwing him across the branch of a tree, and suffering the hounds to bay at him for some minutes before he is thrown among them; the intention of which is to make them more eager, and to let in the tail-hounds; during this interval also they recover their wind, and are apt to eat him more readily. Our author, however, advises not to keep him too long, as he supposes that the hounds have not any appetite to eat him longer than while they are angry with him.

2. *Under ground.* In case a fox does so far escape as to earth, countrymen must be got together with shovels, spades, mattocks, pickaxes, &c. to dig him out, if they think the earth not too great. They make their earths as near as they can in ground that is hard to dig, as in clay, stony ground, or amongst the roots of trees; and their earths have commonly but one hole, and that is straight a long way in before you come at their couch. Sometimes craftily they take possession of a badger's old burrow, which hath a variety of chambers, holes, and angles.

Now to facilitate this way of hunting the fox, the huntsman must be provided with one or two terriers to put into the earth after him, that is, to fix him into an angle; for the earth often consists of many angles: the use of the terrier is to know where he lies; for as soon as he finds him, he continues baying or barking, so that which way the noise is heard that way dig to him. Your terriers must be garnished with bells hung in collars, to make the fox bolt the sooner; besides, the collars will be some small defence to the terriers.

The instruments to dig withal are these: a sharp-pointed spade, which serves to begin the trench where the ground is hardest and broader tools will not so well enter; the round hollowed spade, which is useful to dig among roots, having very sharp edges; the broad flat spade to dig withal, when the trench has been pretty well opened, and the ground softer; mattocks and pickaxes to dig in hard ground, where a spade will do but little service; the coal-rake to cleanse the hole, and to keep it from stopping up; clamps, wherewith you may take either fox or badger out alive to make sport with afterwards. And it would be very convenient to have a pail of water to refresh your terriers with, after they are come out of the earth to take breath.

Hare-Hunting. As, of all chases, the hare makes the greatest pastime, so it gives no little pleasure to see the craft of this small animal for her self-preservation. If it be rainy, the hare usually takes to the high-ways; and if she come to the side of a young grove, or spring, she seldom enters, but squats down till the hounds have over-shot her; and then she will return the very way she came, for fear of the wet and dew that hangs on the boughs. In this case, the huntsman ought to stay an hundred paces before he comes to the wood-side, by which means he will perceive whether she return as aforesaid; which if she do, he must halloo in his hounds; and call them back; and that presently, that the hounds may not think it the counter she came first.

The next thing that is to be observed, is the place

where the hare sits, and upon what wind she makes her form, either upon the north or south wind: she will not willingly run into the wind, but run upon a-side, or down the wind; but if she form in the water, it is a sign she is foul and measles: if you hunt such a one, have a special regard all the day to the brook-sides; for there, and near plashe, she will make all her crossings, doublings, &c.

Some hares have been so crafty, that as soon as they have heard the sound of a horn, they would instantly start out of their form, though it was at the distance of a quarter of a mile, and go and swim in some pool, and rest upon some rush-bed in the midst of it; and would not stir from thence till they have heard the sound of the horn again, and then have started out again, swimming to land, and have stood up before the hounds four hours before they could kill them, swimming and using all subtilties and crossings in the water. Nay, such is the natural craft and subtilty of a hare, that sometimes after she has been hunted three hours, she will start a fresh hare, and squat in the same form. Others having been hunted a considerable time, will creep under the door of a sheep-cot, and hide themselves among the sheep; or, when they have been hard hunted, will run in among a flock of sheep, and will by no means be gotten out from among them till the hounds are coupled up, and the sheep driven into their pens. Some of them (and that seems somewhat strange) will take the ground like a coney, and that is called *going to the vault*. Some hares will go up one side of the hedge and come down the other, the thickness of the hedge being the only distance between the courses. A hare that has been sorely hunted, has got upon a quickset-hedge, and ran a good way upon the top thereof, and then leapt off upon the ground. And they will frequently betake themselves to furz bushes, and will leap from one to the other, whereby the hounds are frequently in default.

Having found where a hare hath relieved in some pasture or corn field, you must then consider the season of the year, and what weather it is: for if it be in the spring-time or summer, a hare will not then set in bushes, because they are frequently infested with pismires, snakes, and adders; but will set in corn-fields, and open places. In the winter-time, they set near towns and villages, in tufts of thorns and brambles, especially when the wind is northerly or southerly. According to the season and nature of the place where the hare is accustomed to sit, there beat with your hounds, and start her; which is much better sport than trailing of her from her relief to her form.

After the hare has been started and is on foot, then step in where you saw her pass, and halloo in your hounds, until they have all undertaken it and go on with it in full cry: then recheat to them with your horn, following fair and softly at first, making not too much noise either with horn or voice; for at the first, hounds are apt to overshoot the chase through too much heat. But when they have run the space of an hour, and you see the hounds are well in with it, and stick well upon it, then you may come in nearer with the hounds, because by that time their heat will be cooled, and they will hunt more soberly. But above all things, mark the first doubling, which must be your direction for the whole day; for all the doublings

Hunting. that she shall make afterwards will be like the former; and according to the policies that you shall see her use, and the place where you hunt, you must make your compasses great or little, long or short, to help the defaults, always seeking the moistest and most commodious places for the hounds to scent in.

To conclude: Those who delight in hunting the hare must rise early, lest they be deprived of the scent of her foot-steps.

Hart or Stag HUNTING. Gefner, speaking of hart-hunting, observes, that this wild, deceitful, and subtle beast, frequently deceives its hunter by windings and turnings. Wherefore the prudent hunter must train his dogs with words of art, that he may be able to set them on and take them off again at pleasure.

First of all, he should encompass the beast in her own layer, and so unharbour her in the view of the dogs, that so they may never lose her slot or footing. Neither must he set upon every one, either of the herd or those that wander solitary alone, or a little one; but partly by sight, and partly by their footing and fumets, make a judgment of the game, and also observe the largeness of his layer.

The huntsman, having made these discoveries in order to the chace, takes off the couplings of the dogs; and some on horseback, others on foot, follow the cry, with the greatest art, observation, and speed; remembering and intercepting him in his subtle turnings and headings; with all agility leaping hedges, gates, pales, ditches; neither fearing thorns, down hills, nor woods, but mounting fresh horse if the first tire. Follow the largest head of the whole herd, which must be singled out of the chace; which the dogs perceiving, must follow; not following any other. The dogs are animated to the sport by the winding of horns, and the voices of the huntsmen. But sometimes the crafty beast sends forth his little squire to be sacrificed to the dogs and hunters, instead of himself, lying close the mean time. In this case, the huntsman must sound a retreat, break off the dogs, and take them in, that is, leam them again, until they be brought to the fairer game; which riseth with fear, yet still striveth by flight, until he be wearied and breathless. The nobles call the beast *a wise hart*, who, to avoid all his enemies, runneth into the greatest herds, and so brings a cloud of error on the dogs, to obstruct their farther pursuit; sometimes also bearing some of the herd into his footings, that so he may the more easily escape by amusing the dogs. Afterwards he betakes himself to his heels again, still running with the wind, not only for the sake of refreshment, but also because by that means he can the more easily hear the voice of his pursuers whether they be far from him or near to him. But at last being again discovered by the hunters and sagacious scent of the dogs, he flies into the herds of cattle, as cows, sheep, &c. leaping on a cow or ox, laying the fore-parts of his body thereon, that so touching the earth only with his hinder feet, he may leave a very small or no scent at all behind for the hounds to discern. But their usual manner is, when they see themselves hard beset and every way intercepted, to make force at their enemy with their horns, who first comes upon him, unless they be prevented by spear or sword. When the beast is slain, the huntsman with his horn windeth the fall of the beast; and then the whole com-

Hunting. pany comes up, blowing their horns in triumph for such a conquest; among whom, the skilfullest opens the beast, and rewards the hounds with what properly belongs to them, for their future encouragement; for which purpose the huntsmen dip bread in the skin and blood of the beast to give to the hounds.

It is very dangerous to go in to a hart at bay; of which there are two sorts, one on land and the other in water. Now, if the hart be in a deep water, where you cannot well come at him, then couple up your dogs; for should they continue long in the water, it would endanger their submerging or foundering. In this case, get a boat, and swim to him, with dagger drawn, or else with rope that has a noose, and throw it over his horns: for if the water be so deep that the hart swims, there is no danger in approaching him; otherwise you must be very cautious.

As to the land-bay, if a hart be burnished, then you must consider the place; for if it be in a plain and open place, where there is no wood nor covert, it is dangerous and difficult to come in to him; but if he be on a hedge-side, or in a thicket, then, while the hart is staring on the hounds, you may come softly and covertly behind him, and cut his throat. If you miss your aim, and the hart turn head upon you, then take refuge at some tree; and when the hart is at bay, couple up your hounds; and when you see the hart turn head to fly, gallop in roundly to him, and kill him with your sword.

Directions at the Death of a Hart or Buck. The first ceremony, when the huntsman comes in to the death of a deer, is to cry "ware haunch," that the hounds may not break in to the deer; which being done, the next is the cutting his throat, and there bleeding the youngest hounds, that they may the better love a deer, and learn to leap at his throat: then the mort having been blown, and all the company come in, the best person who hath not taken say before, is to take up the knife that the keeper or huntsman is to lay across the belly of the deer, some holding by the fore legs, and the keeper or huntsman drawing down the pizzle, the person who takes say, is to draw the edge of the knife leisurely along the middle of the belly, beginning near the brisket, and drawing a little upon it, enough in the length and depth to discover how fat the deer is; then he that is to break up the deer, first slits the skin from the cutting of the throat downwards, making the arber, that so the ordure may not break forth, and then he paunches him, rewarding the hounds with it.

In the next place, he is to present the same person who took say, with a drawn hanger, to cut off the head of the deer. Which being done, and the hounds rewarded, the concluding ceremony is, if it be a stag, to blow a triple mort; and if a buck, a double one; and then all who have horns, blow a recheat in concert, and immediately a general whoop, whoop.

Otter-HUNTING is performed with dogs, and also with a sort of instruments called *otter-spears*; with which when they find themselves wounded, they make to land, and fight with the dogs, and that most furiously, as if they were sensible that cold water would annoy their green wounds.

There is indeed craft to be used in hunting them; but they may be caught in snares under water, and by river-sides: but great care must be taken, for they bite

Hunting. bite sorely and venomously; and if they happen to remain long in the snare, they will not fail to get themselves free by their teeth.

In hunting them, one man must be on one side of the river, and another on the other, both beating the banks with dogs; and the beast not being able to endure the water long, you will soon discover if there be an otter or not in that quarter; for he must come out to make his spraints, and in the night sometimes to feed on grass and herbs.

If any of the hounds finds out an otter, then view the soft grounds and moist places, to find out which way he bent his head: if you cannot discover this by the marks, you may partly perceive it by the spraints; and then follow the hounds, and lodge him as a hart or deer. But if you do not find him quickly, you may imagine he is gone to couch somewhere farther off from the river; for sometimes they will go to feed a considerable way from the place of their rest, choosing rather to go up the river than down it. The persons that go a-hunting otters, must carry their spears, to watch his vents, that being the chief advantage; and if they perceive him swimming under water, they must endeavour to strike him with their spears, and if they miss, must pursue him with the hounds, which, if they be good and perfectly entered, will go chanting and trailing along by the river-side, and will beat every root of a tree, and osier-bed, and tuft of bulrushes; nay, they will sometimes take water, and bait the beast, like a spaniel, by which means he will hardly escape.

Roe-buck HUNTING is performed divers ways, and very easily in the woods.

When chased, they usually run against the wind, because the coolness of the air refreshes them in their course; therefore the huntsmen place their dogs with the wind: they usually, when hunted, first take a large ring, and afterwards hunt the hounds. They are also often taken by counterfeiting their voice, which a skilful huntsman knows how to do by means of a leaf in his mouth. When they are hunted, they turn much and often, and come back upon the dogs directly; and when they can no longer endure, they take foil, as the hart does, and will hang by a bough in such a manner, that nothing of them shall appear above the water but their snout, and they will suffer the dogs to come just upon them before they will stir.

The venison of a roe-buck is never out of season, being never fat, and therefore they are hunted at any time; only that some favour ought to be shown the doe while she is big with fawn, and afterwards till her fawn is able to shift for himself; but some roe-does have been killed with five fawns in their bellies.

He is not called, by the skilful in the art of hunting, a *great roe-buck*, but a *fair roe-buck*; the herd of them is called a *bevy*: and if he hath not bevy-grease upon his tail, when he is broken up, he is more fit to be dog's meat than man's meat. The hounds must be rewarded with the bowels, the blood, and feet slit asunder, and boiled all together; this is more properly called a *dose* than a *reward*.

HUNTING-Match. The first thing that is to be considered by one who designs to match his horse for his own advantage, and his horse's credit, is not to flatter himself with the opinion of his horse, by fancying

Hunting. that he is a swift, when he is but a slow gallopper; and that he is a whole-running-horse, that is, that he will run four miles without a sob at the height of his speed, when he is not able to run two or three. Very probably some gentlemen are led into this error, by their being mistaken in the speed of their hounds, who, for want of trying them against other dogs that have been really fleet, have supposed their own to be so, when in reality they are but of a middling speed; and because their horse, when trained, was able to follow them all day, and upon any hour, to command them upon deep as well as light earths, have therefore made a false conclusion, that their horse is as swift as the best; but, upon trial against a horse that has been rightly trained after hounds that were truly fleet, have bought their experience perhaps full dear. Therefore it is advisable for all lovers of hunting to procure two or three couple of tried hounds, and once or twice a week to follow after them at train-scent; and when he is able to top them on all sorts of earth, and to endure heats and colds stoutly, then he may better rely on his speed and toughness.

That horse which is able to perform a hare-chase of five or six miles briskly and courageously, till his body be as it were bathed in sweat; and then, after the hare has been killed, in a nipping frosty morning, can endure to stand till the sweat be frozen on his back, so that he can endure to be pierced with the cold as well as the heat; and then, even in that extremity of cold, to ride another chase as briskly, and with as much courage as he did the former; that horse which can thus endure heats and colds is most valued by sportsmen. Therefore, in order to make a judgment of the goodness of a horse, observe him after the death of the first hare, if the chase has been any thing brisk: if, when he is cold, he shrinks up his body, and draws his legs up together, it is an infallible sign of want of vigour and courage: the like may be done by the slackening of his girths after the first chase, and from the dulness of his teeth, and the dulness of his countenance, all which are true tokens of faintness and being tired; and such a horse is not to be relied on in case of a wager.

Here it will not be improper to take notice of the way of making matches in former times, and the modern way of deciding wagers. The old way of trial was, by running so many train-scents after hounds, as was agreed upon between the parties concerned, and a bell-course, this being found not so uncertain, but more durable than hare hunting; and the advantage consisted in having the trains led on earth most suitable to the qualifications of the horses. But now others choose to hunt the hare till such an hour, and then to run this wild-goose chase; a method of racing that takes its name from the manner of the flight of wild-geese, which is generally one after another; so the two horses, after running of twelvescore yards, had liberty, which horse soever could get the leading, to ride what ground he pleased, the hindmost horse being bound to follow him, within a certain distance agreed on by articles, or else to be whipped up by the triers or judges which rode by; and whichever horse could distance the other won the match.

But this chase, in itself very inhuman, was soon found to be very destructive to good horses, especially when two good horses were matched; for neither being able

Hunting, to distance the other till both were ready to sink under their riders through weakness, oftentimes the match was fain to be drawn and left undecided, though both the horses were quite spoiled.

Hunting-
tonshire.

This brought up the custom of train-scents, which afterwards was changed to three heats and a straight course; and that the lovers of horses might be encouraged to keep good ones, plates have been erected in many places in Britain. The fewer of these before you come to the course, if your horse be fiery and mettled, the better; and the shorter the distance, the better. Also, above all things, be sure to make your bargain to have the leading of the first train; and then make choice of such grounds where your horse may best show his speed, and the fleetest dogs you can procure: give your hounds as much law before you as your triers will allow, and then, making a loose, try to win the match with a wind; but if you fail in this attempt, then bear your horse, and save him for the course; but if your horse be slow, but well-winded, and a true spurred nag, then the more train-scents you run before you come to the straight course, the better. But here you ought to observe to gain the leading of the first train; which in this case you must lead upon such deep earths, that it may not end near any light ground; for this is the rule received among horsemen, that the next train is to begin where the last ends, and the last train is to be ended at the starting place of the course; therefore remember to end your last on deep earths, as well as the first.

HUNTINGDON, the county-town of Huntingdonshire in England, seated upon an easy ascent, on the north side of the river Ouse. It was made a free borough by king John, consisting of a mayor, 12 aldermen, burgesses, &c. by whom the two members of parliament are chosen. It had anciently 15 parishes, and has now but two; in one of which, called *St John's*, Oliver Cromwell was born, in 1599. Here was formerly a castle, built by William the Conqueror, which afterwards belonged to David, a prince of Scotland, with the title of *earl*; but Henry VIII. gave it to George Hastings, with the earldom annexed, in whose family it still continues. It stands in the great north road; and has a bridge built of free-stone over the Ouse, which is made navigable for small vessels as high as Bedford. It is the place where the assizes are kept, and where the county-jail stands. It has a good market-place, and several convenient inns, besides a grammar-school; and is very populous. W. Long. $\circ$. 15. N. Lat. 52. 23.

HUNTINGDONSHIRE, a county of England, bounded on the south by Bedfordshire; on the west by Northamptonshire, as also on the north; and by Cambridgeshire on the east; extending 36 miles in length from north to south, 24 in breadth from east to west, and near 67 in circumference. This county, which is in the diocese of Lincoln, is divided into four hundreds, and contains 6 market-towns, 29 vicarages, 78 parishes, 279 villages, about 8220 houses, and upwards of 41,000 inhabitants; but sends only four members to parliament, namely, two knights of the shire, and two members for Huntingdon. It is a good corn country; and abounds in pastures, especially on the eastern side, which is fenny. The rest is diversified by rising hills and shady groves, and the river Ouse waters the southern part.

The air of this county is in most parts pleasant and wholesome, except among the fens and meres, though they are not so bad as the hundreds of Kent and Essex. The soil is fruitful, and produces great crops of corn, and the hilly parts afford a fit pasture for sheep. They have great numbers of cattle; and plenty of water-fowl, fish, and turf for firing; which last is of great service to the inhabitants, there being but little wood, though the whole county was a forest in the time of Henry II. The only river besides the Ouse is the Nen, which runs through Whittlesey Mere.

HU QUANG, a province of the kingdom of China, in Asia, which has a great river called *Tang*, and *Tse-chiang*, which runs across it from east to west. It is divided into the north and south parts, the former of which contains eight cities of the first rank, and 60 of the second and third; and the latter, seven of the first rank, and five of the second and third. It is a flat, open country, watered every where with brooks, lakes, and rivers, in which there are great numbers of fish. Here is plenty of wild-fowls; the fields nourish cattle without number, and the soil produces corn, and various kinds of fruits. There is gold found in the sands of the rivers; and in the mines they have iron, tin, &c. In short, there is such a variety of all sorts of commodities, that it is called *the magazine of the empire*.

HURA, in botany: A genus of the monadelphia order, belonging to the monœcia class of plants; and in the natural method ranking under the 38th order, *Tricocca*. The amentum of the male is imbricated, the perianthium truncated: there is no corolla; the filaments are cylindrical, peltated on top, and surrounded with numerous or double antheræ. The female has neither calyx nor corolla; the style is funnel-shaped; the stigma cleft in twelve parts; the capsule is twelve-celled, with a single seed in each cell. There is but one species, *viz.* the crepitans, a native of the West Indies. It rises with a soft ligneous stem to the height of 24 feet, dividing into many branches, which abound with a milky juice, and have scars on their bark where the leaves have fallen off. The male flowers come out from between the leaves upon foot-stalks three inches long; and are formed into a close spike or column, lying over each other like the scales of fish. The female flowers are situated at a distance from them; and have a long funnel-shaped tube spreading at the top, where it is cut into 12 reflected parts. After the flower, the germen swells, and becomes a round compressed ligneous capsule, having 12 deep furrows, each being a distinct cell, containing one large round compressed seed. When the pods are ripe, they burst with violence, and throw out their seeds to a considerable distance. It is propagated by seeds raised on a hot-bed; and the plants must be constantly kept in a stove. The kernels are said to be purgative, and sometimes emetic.

HURDLE, is the name of a sledge used to draw traitors to the place of execution.

HURDLES, in fortification, are made of twigs of willows or osiers interwoven close together, sustained by long stakes. They are made in the figure of a long square, the length being five or six feet, and the breadth three and an half. The closer they are wattled together, the better. They serve to render the batteries firm, or to consolidate the passage over muddy ditches; or to cover traverses and lodgments for the defence of the workmen against fire-works or stones thrown against them.

The

Hurdles.

Hurds
Hurricane.

Hurricane.
Husband.

The Romans had a kind of military execution for mutineers, called *putting to death under the hurdle*. The manner of it was this: The criminal was laid at his length in a shallow water, under an hurdle, upon which was heaped stones, and so pressed down till he was drowned.

HURDLES, in husbandry, certain frames made either of split timber, or of hazle-rods wattled together, to serve for gates in inclosures, or to make sheep-folds, &c.

HURDS, or HORDS, of flax or hemp; the coarser parts separated in the dressings from the tear, or fine stuff. See FLAX.

HURL-BONE, in a horse, a bone near the middle of the buttock, very apt to go out of its sockets with a hurt or strain.

HURLERS, a number of large stones, set in a kind of square figure near St Clare in Cornwall, so called from an odd opinion held by the common people, that they are so many men petrified, or changed into stones, for profaning the sabbath-day by hurling the ball, an exercise for which the people of that country have been always famous.

The hurlers are oblong, rude, and unhewed. Many authors suppose them to have been trophies erected in memory of some battle; others take them for boundaries to distinguish lands. Lastly, others, with more probability, hold them to have been sepulchral monuments.

HURLY-BURLY, in vulgar language, denotes confusion or tumult, and is said to owe its origin to two neighbouring families, Hurleigh and Burleigh, which filled their part of the kingdom with contest and violence.

HURON, a vast lake of North-America, situated between 84° and 89° W. Long. and between 43° and 46° of N. Lat. from whence the country contiguous to it is called *the country of the Hurons*, whose language is spoken over a great extent in the southern parts of America.

HURRICANE, a general name for any violent storm of wind; but which is commonly applied to those storms which happen in the warmer climates, and which greatly exceed the most violent storms known in this country. The ruin and desolation accompanying a hurricane (says Dr Mosely†) cannot be described. Like fire, its resistless force consumes every thing in its track, in the most terrible and rapid manner. It is generally preceded by an awful stillness of the elements, and a closeness and mistiness in the atmosphere, which makes the sun appear red, and the stars larger. But a dreadful reverse succeeding—The sky is suddenly overcast and wild—The sea rises at once from a profound calm into mountains—The wind rages and roars like the noise of cannon—The rain descends in deluges—A

† Treatise
on Tropical
Diseases,
&c. 8vo.

dismal obscurity envelopes the earth with darkness—The superior regions appear rent with lightning and thunder—The earth often does and always seems to tremble—Terror and consternation distract all nature—Birds are carried from the woods into the ocean; and those whose element is the sea, seek for refuge on land—The frightened animals in the field assemble together, and are almost suffocated by the impetuosity of the wind in searching for shelter; which, when found, serves them only for destruction—The roofs of houses are carried to vast distances from their walls, which are beat to the ground, burying their inhabitants under them—Large trees are torn up by the roots, and huge branches shivered off, and driven through the air in every direction, with immense velocity—Every tree and shrub that withstands the shock, is stripped of its boughs and foliage—Plants and grass are laid flat on the earth—Luxuriant spring is changed in a moment to dreary winter—This direful tragedy ended, when it happens in a town, the devastation is surveyed with accumulated horror: the harbour is covered with wrecks of boats and vessels; and the shore has not a vestige of its former state remaining. Mounds of rubbish and rafters in one place, heaps of earth and trunks of trees in another, deep gullies from torrents of water, and the dead and dying bodies of men, women, and children, half buried, and scattered about, where streets but a few hours before were, present the miserable survivors with a shocking conclusion of a spectacle to be followed by famine, and when accompanied by an earthquake, by mortal diseases.

These destructive phenomena are now thought to arise from electricity, though the manner in which it acts in this case is by no means known. It seems probable, indeed, that not only hurricanes, but even the most gentle gales of wind, are produced by the action of the electric fluid; for which see the articles WIND, WHIRLWIND, &c.

HURST, HYRST, or HERST, are derived from the Saxon *byrst*, i. e. *a wood, or grove of trees*. There are many places in Kent, Suffex, and Hampshire, which begin and end with this syllable; and the reason may be, because the great wood called *Andreswald* extended through those countries.

HURST-Castle, a fortress of Hampshire in England, not far from Limington. It is seated on the extreme point of a neck of land which shoots into the sea, towards the isle of Wight, from which it is distant two miles.

HUSBAND, a man joined or contracted with a woman in marriage. See MARRIAGE.

HUSBAND Land, a term used in Scotland for a portion of land containing six acres of sock and scythe land; that is, of land that may be tilled with a plough, and mowen with a scythe.

H U S B A N D R Y,

THE business of a farmer, or of one who lives by cultivating the ground. In this view it includes not only agriculture, but several other branches connected with it, such as the rearing of cattle, the management of the dairy, making butter and cheese, raising flax, timber, &c. the management of bees, and a num-

ber of other articles which it is difficult to enumerate particularly.

Agriculture, properly so called, treats only of the Difference cultivation of different soils, and preparing them for yielding the largest crop of any kind of vegetable; but it belongs to husbandry to make choice of the soil most proper

proper for each different vegetable, and to manage matters so that each soil may carry what it is best adapted for, so that on the whole the produce of the farm may be as advantageous as possible. In like manner, the husbandman must know what crops are most proper to be raised in the country where he lives, either with a view to sale or to provender for cattle. The rearing of these, indeed, constitutes one of the most essential articles of husbandry; it being requisite that the husbandman should know not only how to feed them properly, but how to keep them free from diseases, and to distinguish the best breeds, so that such as are designed for work may be capable of doing the most at least expence, and those designed for sale may with the least trouble be brought in good condition to market, and afford the greatest profit to himself as well as the best bargain to the purchaser.

2
It is the interest of a husbandman to render provisions as cheap as possible.

It is by means of the husbandman only that all the inhabitants of a country are enabled to live; whence it ought to be a consideration with him to cultivate the ground in such a manner, as may enable him to afford the produce at the lowest price. Thus he will also consult his own interest: for cheapness of provisions is the only true means by which the population of any country can be advanced; and the greater the number of inhabitants, the greater market will the husbandman have for his goods. Indeed, by a certain mode of arguing, it may be imagined, that it would be more advantageous to keep up provisions at as high a price as possible, rather than to lower them: but however this may apply to manufactures of various kinds, it never can apply to husbandry; for by raising the price of provisions, the price of every other thing also is raised, and it becomes more difficult for the husbandman himself to live, as well as others.

3
Of societies for encouraging various branches of husbandry.

Thus the business of an husbandman is not only extremely complicated and difficult, but important also; insomuch, that societies have been lately instituted in many different parts of the kingdom for its advancement, and premiums offered to those who excelled in any particular branch. Some of these premiums are held out for raising the greatest quantity of particular kinds of vegetables; others for gaining the greatest extent of ground from the sea: some for improving waste ground; others for the invention of the most useful machines for harrowing, sowing, and various operations in agriculture. But though the intention of these societies is undoubtedly laudable and patriotic, and though the invention of man has in a manner been exhausted to accomplish the purposes for which they were instituted; it remains yet a matter of great doubt and uncertainty whether they have really been productive of any public good or not. It does not clearly appear, that the means of subsistence are rendered more generally easy, or that the lives of mankind are more happy and comfortable, than before any societies were instituted, or before any considerable improvements in husbandry were made. On the contrary, provisions of all kinds, instead of becoming cheaper, have gradually become dearer, and their price on the whole is sensibly augmented every four or five years. Hence it is impossible to avoid concluding, that, notwithstanding the apparent improvements which have been made in such numbers, there is not yet any *real* one in the whole art.—Something of this kind has been taken notice of even by the

4
Doubtful how far they have been really useful.

5
Improvements in husbandry more apparent than real.

members of these societies themselves; and on this subject Mr Wimpey expresses himself as follows: Bath Papers, vol. iii. p. 171.

“It is certainly clear from the average prices of corn and provisions of all kinds for 20 years past, that there is not too much land in cultivation. Prices have advanced considerably above what has been deemed, and that justly too, the medium standard. As a manufacturing and commercial country, it is properly the duty of legislature to provide, as far as may be consistently with the liberty of the subject, that the price of provisions may be kept as near as possible to their medium value. This is conceived to be very practicable, even so as to be a convenience to the grower as well as the consumer. Some writers (Locke, Montesquieu, &c.) have supposed, that the advance of commodities in price is rather apparent and nominal than real. Things are not so much, if at all (say they), advanced in price, as it is imagined. The precious metals are exceedingly increased in quantity, and proportionably fallen in value. Possibly there may be some truth in this observation, if we go back some hundreds of years; and if taken upon a scale that comprehends all Europe: but from the term of 40 or 50 years, or even from the time that Mr Locke wrote to the present hour, there is little difference in the value of gold and silver; an ounce of either being of much the same value now as then. The frequent and sudden changes that take place in the price of corn and other commodities, which are sometimes at double the price one year they were the foregoing, must be owing to some other cause than that above-mentioned, which operates slowly, if at all, and is not perceptible in less than a century.

“If the quantity of corn and provisions at market always has borne the same proportion to the demand there is for them, the price would be always invariably and unchangeably the same. The variation of the prices, therefore, is governed by the variation of the said proportion. If the demand be greater and the quantity the same, or the demand the same and the quantity less, the price must necessarily advance; and *vice versa*, if the quantity should increase, and the demand remain the same, the price must as necessarily fall; and it is not in the power of man to make it otherwise. But though this immutable relation is beyond our power to alter, we can by art and industry augment the quantity, and thereby lower the price; cheapness being an infallible consequence of plenty, which is the direct object of an improving cultivation. This is a matter of great consequence to the poor labourer, the manufacturer, and the merchant; and no disadvantage to the grower; because, what he would lose by the fall of price, he would gain by the increased consumpt.

“It is not easy to conceive how many and how great the improvements are which have been made in this most important of all arts in the course of the present century. A patriotic spirit of uncommon ardour hath gone forth; and the nobility and gentry, like the senators of Rome, have set, as it were, their hands to the plough, and excited their tenants and neighbours to practices of which they had no idea before. Yea, they have done more; they have instituted societies, and made them receptacles and distributors of useful knowledge; they have raised subscriptions, and added marks of honour and pecuniary advantages to the rewards which naturally result from the attention and industry of

7
Why those who have gained premiums from societies have not been of any real service to the country.

of the ingenious artist. But it must be allowed, that though much has been done, there still remains much more to be done. Experimenters have not always (perhaps but seldom) entered into the views, and ably seconded the intentions, of those valuable institutions. Animated with the hope of obtaining the premiums held out by dint of extraordinary exertions, expensive manures, and a concurrence of fortunate circumstances, more the effect of chance than of design, they often have been the successful adventurers, though at the same time entirely ignorant to what causes they owed their success. We too often indeed ascribe effects to causes which are no way connected with them. The practice of such men is more like the nostrums of quacks, than the recipes of a regular physician. The medicine may be good; but, being ignorant of principles, they know not how to accommodate it as circumstances may require."

8
Improve-
ments made
in husban-
dry hither-
to attended
with no
profit.

Considerations of this kind must certainly lead us to suppose, that most, if not all, the improvements made in husbandry for a long time past, are too expensive; and that, though by their means larger crops are now obtained than formerly, the profits are more than swallowed up by the enormous sums required to produce them. Hence we have as yet obtained only larger or more elegantly formed *beasts* of different kinds; and whether this acquisition is ultimately to be considered as *profitable*, remains yet to be determined. Unfortunately this sentiment seems to be confirmed by taking a review of the agricultural improvements made during the last half-century. These are:

Bath Pa-
pers, vol. 5.
9
Account of
the im-
provements
in agricul-
ture for the
last half
century.

1. *Improvements in the Art of Tillage.* Improvements of this kind consist in more perfectly breaking and pulverising the soil, and keeping it more free from weeds than formerly. Mr Jethro Tull was the author of these, and showed the advantages thence arising. By frequent turning over and pulverising the soil, we not only destroy the weeds very effectually, but likewise grubs, beetles, worms, and maggots of many different kinds. "Nothing (says Mr Wimpey) so effectually prevents the ravages of the several tribes of subterraneous insects as the frequent stirring and crumbling the ground: I have had large patches of several poles square in a field of beans destroyed by the grub of the cock-chaffer; and many hundreds of cabbage-plants by a grey grub of smaller size. Both these execute their mischief underground. The former eat the roots of the beans even when in kid; and then they wither, fall, and die: the latter bites off the stem of the plant just under the surface, and does infinite mischief: but I have always found tillage, duly performed, capable of destroying the whole race."

2. *Invention of new Implements of Husbandry, or improvements of the old.* This class includes all the new invented ploughs, harrows, horse and hand-hoes, &c. by means of which it is generally supposed that the work of tillage can be performed at much less expence, as well as more effectually, than formerly.

3. *Sowing a great quantity of Seed in sowing, and the production of better Crops, by the more regular distribution of what is sown.* This improvement chiefly consists in drilling, instead of sowing in the broad-cast way as formerly. The gain is here evident; and Mr Wimpey calculates it at a tenth or twelfth part of the whole produce: and if the community are not yet sensible of

VOL. VIII. Part II.

any advantage from such a considerable saving, it must be because the drilling husbandry has not yet become very general.

4. *Suiting the Crop to the Nature and Condition of the Soil.* The farmer is now enabled to this better than formerly, by the introduction of a number of new-vegetables formerly unknown. Thus, as there are many grounds very unfit for the production of wheat, there is now no occasion for reaping scanty crops of it from such as are little adapted to the raising of that grain; because another article, for which perhaps there was formerly no demand, may now be raised with considerable profit on a soil where wheat will not grow to any advantage.

5. *The Rotation of Crops.* Thus a very considerable addition is made to the produce of the ground by keeping it perpetually fertile; whereas formerly it was often worn out and rendered barren by too frequent cropping, when a proper rotation was not known.

6. *The Introduction of new Manures.* These are principally lime and marle; of the action of which an account is given under the article AGRICULTURE, n° 20.

7. *The Introduction of many new Articles into Field-Culture.* These, whatever profit they may yield to the farmer, consist principally of provender for cattle. They ought, however, to have a considerable effect in producing plentiful harvests, as hereby the cattle may be supposed to do their work more perfectly, and to be maintained at less expence than before.

8. *The Application of these to the rearing and fattening of Cattle.* The good effects of this ought to be felt partly in the manner mentioned in the former article, and partly in lowering the price of flesh-meat, and consequently of all other kinds of provisions.

Thus we see, that in the course of half a century, methods have been found of eradicating weeds, destroying insects, saving vast quantities of seed-corn, of suiting the crops to the soil, of using new manures, raising new plants; and all this, together with multitudes of new machines for performing in a better manner the operations of agriculture, has apparently amounted to mere nothing. The price of provisions seems to have begun to rise with the improvements, and to be continually advancing. It is by no means in our power to point out particularly the causes of so disagreeable an event. It must, however, undoubtedly depend on some miscalculation, or over-rating the profits which have arisen from those improvements: whence the landholders have uniformly been induced to raise their rents, while the farmers, finding their expences greatly augmented, not only on account of the advance of rent, but likewise from the more costly modes of tillage, have been obliged to augment the prices of their grain beyond what the increased influx of money into the kingdom would bear.—Such miscalculations are not uncommon in every business. A manufacturer is apt to be enticed by a certainty of having an increase of his goods in a given time: but frequently, when improvements are tried, it is found that the absolute expence, or the quantity of labour requisite to produce the increase, is greater than the augmentation of profit can bear; and he is afterwards, with regret and loss, obliged to lay aside the improvements from which he had once such hopes. In like manner, we fear, it has fared with the husbandman. The improvements

16
Little ad-
vantage re-
sulting from
the whole.

17
Conjectures
concerning
the causes.

in husbandry originated principally among the landholders; whose principal view, we may suppose, was an augmentation of rent. The tenants were obliged to attempt improvements in order to pay the advance, as well as by the express order of their landlords. Hence they were induced to keep a great number of horses, that their lands might be tilled with sufficient expedition, and in a more perfect manner than before. The oxen, formerly made use of, and which answered the purposes both of provision and labour, were discarded, and a set of most expensive animals, useless except for the purposes of labour or pleasure, introduced in their stead. A vast quantity of grain, which ought to have sustained the human species, was thus bestowed on the brute creation: and though this might in some measure be supposed to be counteracted by the increase of crop in consequence of employing horses, it is evident that it has not answered the general expectation; since we may say, that the farmers have not been able to pay one penny of advanced rent without advancing also the price of their grain.

¹²
Of the rearing of cattle.

With regard to the rearing of cattle, the case is equally doubtful. The most extravagant prices have been given for the best breeds as they are called; but it remains yet to be proved, that these breeds are really more useful to the country than the smaller ones. The expence of keeping them is undoubtedly greater, and this expence is enhanced by the large cattle being generally less hardy than the smaller. It seems, besides, impossible that one large horse, for instance, can be equally useful with two small ones, even though he should be as strong as both; for this plain reason, that two horses, though ever so small, can be put to two different kinds of work at once, which cannot be done with the largest single horse imaginable. The like is applicable to black cattle: We cannot suppose the largest single ox to be equal to two ordinary oxen, though he may perhaps require more to fatten him than would bring to market three or four of an ordinary quality; and so of other animals.

¹³
Of the other improvements in husbandry.

It is much to be feared that the same reasoning extends to most of the improvements hitherto made in husbandry. The vegetative powers of the earth cannot be made always to exert themselves to the utmost, without an expence which the increase of produce can by no means balance. By a total neglect of culture, indeed, the soil will produce little or nothing; by a moderate degree of culture the product will be greatly augmented, the farmer will be enabled to pay his rent, and at the same time to afford his grain at such a price as can allow the labourers to live comfortably: but if we go on with extraordinary methods of culture, expecting to increase the produce of the soil, and to be able to exact an augmentation of rent *ad infinitum*, we will certainly be deceived; for thus the price of provisions must be infinitely increased also. Thus, indeed, the produce of the ground will be somewhat increased, but the farmer will ultimately be a loser; so that, to save himself from ruin, he must at last burthen the public both with his advanced rent and the expence of most of his improvements, by advancing the price of grain and of all kinds of provisions.

Such seem in general to be the reasons why the country has reaped so little advantage by the improvements

made of late in the affairs of agriculture and husbandry. If experiments are now to be made, it is plain that they ought to be with a view to determine that medium of culture which the ground can bear with the greatest profit, comparing the expence and produce of the two different modes together; and that mode which is the least expensive ought undoubtedly to be chosen, even though attended with no more profit than that which is executed at a greater expence. Thus, if a farmer, by laying out 5 *l.* can produce a crop equivalent to 7 *l.* he ought undoubtedly to prefer that to a mode of cultivation by which he lays out seven to procure nine. Nay, though by his new method he should procure 9 *l.* 10 *s.* by laying out 7 *l.* it would still be evidently for the good of the community that the former method were followed. The reason of this is, that every expence of the husbandman, as well as of every other, must ultimately be defrayed by the community at large. Thus if the husbandman employs a greater number of hands than would otherwise be necessary, it is plain that the expence of these must be defrayed by the community, not only because of the provisions they must necessarily consume, but because each of these, were he not employed in that particular way, might contribute in some other towards his own support and that of others: and the very same may be said of the farmer who employs a greater number of horses than would otherwise be necessary. Now, in the example just given, the farmer, or the community at large, by laying out 5 *l.* gain 40 *s.* which is 40 *per cent.*; but in the other case, *viz.* that of expending 7 *l.* for a return of 9 *l.* 10 *s.* the farmer indeed gets 50 *s.* instead of 40 *s.* but the community do not gain equally, having now not quite 36 *per cent.* instead of 40 which they had before.

Hence it becomes evident, that by encouraging individuals to expend large sums on agriculture, and thus diminish the proportion of their own profits, the community must always suffer, and a rise of provisions will infallibly take place, whether the individuals enrich themselves or not. Evils of this nature can be remedied only by the legislature: but it is to be feared that the time is yet very distant when any certain mode of culture will be established by law; and until this happen, it is vain to think that either the speculations or experiments of individuals or of societies will be attended with much benefit to the community, whatever advantage particular persons may sometimes derive from them.—Leaving this subject, therefore, we shall now proceed to those which more immediately relate to the business of husbandry in its present state.

In considering this subject in its full extent, it evidently divides itself into three parts: the *first*, Relating to the cultivation of such vegetables as are proper for the subsistence of mankind or the rearing of cattle; as grain, grass, cabbage, turnips, and other vegetables of that kind: the *second*, Such as belong more particularly to trade and commerce; as flax, hemp, hops, bees, timber, &c. Under both these are included the knowledge of various manures, of the nature of different soils, &c. The *third* part includes, the raising and management of cattle, poultry, of the dairy, with other adventitious articles, less connected with agriculture; of all which we shall now treat in order.

¹⁴
Disadvantage of allowing farmers to expend large sums on agriculture, in order to enrich themselves by a small proportion of profit.

¹⁵
Division of husbandry into three parts.

PART

PART I. Of the VEGETABLES most proper to be raised for the use of the HUMAN SPECIES, or as FOOD for CATTLE.

AMONG those raised for the use of mankind, wheat has universally been supposed to hold the first place, and other kinds of grain to be the next to it; but in modern times, an author of no mean reputation has arisen, who endeavours to prove that wheat ought not to be cultivated, nor bread to be eaten. This is M. Linguet, who has written a treatise expressly upon the subject; and, ridiculous as the assertion may seem, has been thought worthy of a formal refutation by Dr Tiffot.—One of M. Linguet's arguments is, that wheat impoverishes the ground on which it grows: but in opposition to this, Dr Tiffot urges, that corn is more easily cultivated than grass; and that consequently, in the country he speaks of (Switzerland), the best fields are appropriated to hay, and the worst to corn. "If there are some districts of very poor land (says he) almost entirely sown with corn, they are not poor because they produce only corn, but because they are not fit to produce any thing else. Their soil is so bad, that they can grow but very little fodder: consequently they maintain only such cattle as are absolutely necessary for labour; and those are ill fed, and frequently perish. They have but little manure, and their crops are small; for large crops of all sorts can only be expected from lands naturally rich or strongly manured. Thus the poverty of the inhabitants is only owing to their possessing an ungrateful soil.—What proves evidently that it is the natural soil which is in the fault, and not the corn which impoverishes, is, that where there is meadow and arable land, the price of the meadow-land is much more considerable than that of the arable. In most parts of this country the proportion is nearly ten to one; and there are even some meadows, for one part of which they would give 30 of field-lands; and some of vines, for which 100 of arable would be given. Those districts where the soil will produce nothing but corn, are poor; but in those which furnish fodder, and also fine crops of grain, the inhabitants are wealthy and happy, unless they are oppressed by taxes."

M. Linguet draws another objection from the length of time required to cultivate wheat; but Tiffot, by another calculation, shows, that 48 days work throughout the year would cultivate more wheat than is sufficient for a family of six persons. The time necessary for cultivation of arable land also does not increase in proportion to its extent; but in case more is cultivated than is requisite for the subsistence of the family, a trade is formed, which might be increased to an unlimited extent. He then compares the time requisite for the cultivation of vines which are recommended by M. Linguet, and finds it to be much longer than that required for wheat. "I know very well (says he) that the one requires cattle, and the other does not: but these cattle, far from being expensive, will, if properly managed, increase the gain of the farmer; therefore they must not be looked upon as any expence. Corn is subject to many accidents, but vines are subject to many more: those which the vines suffer, sometimes

spoil the vintage for several years; whereas those which happen to arable land, only spoil the crop for the season: and as the expence of cultivating vines, for which only manual labour can be employed, is much more considerable; therefore the *vigneron* (or person who cultivates vines), who engages more largely than the farmer, will consequently be a much greater loser if unsuccessful.—Hay is also subject to frequent and very disagreeable accidents; the securing it is sometimes very difficult; and, when it is badly made, it is very hurtful to cattle.—A single fact will be sufficient to prove the casualties to which hay is subject; *viz.* that it varies in price as much as grain. Accidents of hay-mows taking fire are but too frequent; and this is not to be feared in corn-mows."

The other objections of M. Linguet to wheat appear to be quite frivolous; so that concerning the cultivation of this grain, Dr Tiffot draws the following conclusions: "It appears then, from what has been said, that wheat is not a commodity that is impoverishing in itself; and that this grain will grow indifferently at least in lands and situations which are unfavourable to other plants. This grain is likewise adapted to most climates; and if there are districts almost entirely sown with wheat, and yet poor, it is the fault of the soil, and not of this useful grain."

But the most extraordinary argument perhaps ever thought of on this subject is M. Linguet's assertion, that the use of wheat, or bread made from it, is detrimental to population; and that the countries where this grain is cultivated are poor and thinly inhabited, whereas those which abound with vineyards and pasture-lands are rich and populous. But this, in Dr Tiffot's opinion, shows only that one soil is more rich than another, and that a fertile soil will maintain most inhabitants. "No person (says he) is more capable of assigning the cause of the subjection of the Roman empire to the northern powers, than M. Linguet; but he cannot surely be serious when he says, that they were enabled to conquer them because those northern countries produced no corn, and that population decreased since the introduction of grain. I shall make three observations on this passage: First, the armies of Gustavus Adolphus, Charles XII. and the king of Prussia, whose food was bread, would be as formidable against the Italians of those times, who eat less than was eaten in the days of Scipio, as their ancestors were 1400 years ago against the Romans: and M. Linguet must certainly know, that those Greeks who subsisted on bread, those Romans who eat nothing but bread and vegetables in pottage, subdued all the known world, among whom were many nations who ate less bread than themselves. A Roman soldier's allowance of bread was much greater than what soldiers have at present; and by the use of this food they had much more strength than our modern soldiers can boast of. The allowance to a Roman soldier was 64 pounds of wheat per month; and this he was strictly forbidden

either to sell or exchange. Their soldiers had very seldom any cheese, bacon, or pulse; so that wheat was almost their only food, and the proportion was double what is allowed soldiers in our days. They ate it in bread, in flour-milk, and in thin cakes; and they were not subject to epidemic or putrid disorders, which is too much the case with our modern armies. We may easily judge from the weight of their accoutrements, that the Roman soldiers were not possessed of less personal strength than those which compose the armies at this day; they were not less brave, nor did their food render them in any way unhealthy: on the contrary, where there is such difficulty in procuring a supply of good animal food to an army, as is often the case in modern times, it is probable that reducing them to the simple diet of a Roman soldier would be the most proper method of preventing epidemic diseases among them. Secondly, it is very doubtful whether those countries were more populous formerly than they are at this time; it is even probable that they were less so. Lastly, the people of these northern countries were not without wheat; it was the basis of their food and drink: without quoting other authors who attest it, suffice it to say, that Tacitus affirms it," &c.

In this last particular, however, our author appears to be mistaken; but whatever may be in this, we apprehend that few of our readers will entertain any doubt concerning the wholesomeness of wheat, or the propriety of making it into bread after once it is cultivated. The truly important matter is to determine, whether it be a profitable crop or not for the person who cultivates it? In this respect indeed it has been condemned by the generality of farmers, and dairy-farms are universally supposed to be more profitable than such as produce corn. The vast superiority of the former is set forth by Thomas Davis, Esq; of Long-leat, in the following words. "Experience sufficiently evinces the extreme difficulty of persuading tenants that they get more (generally speaking) by feeding their lands, than by ploughing them; yet it requires very few arguments to convince a landlord, that in cold wet lands especially, the less ploughed land you have, the less you put it in a tenant's power to ruin your estate. That a tenant of 60 l. per annum on a dairy-farm will get money, while a corn farm of the same size will starve its occupier (though perhaps the former gives 15 s. per acre for his land, and the latter only 10 s.), is self-evident. The plough is a friend of every body's, though its advantages are very far from being particularly and locally felt; corn being an article that will bear keeping till the whim or caprice, or supposed advantage of its possessor, call it forth. But the produce of the cow is far otherwise. Cheese must necessarily be sold at a certain period: it is a ponderous article; and one-twelfth, or at least one-fifteenth, of its value, is often paid for carrying it to a fair 50 miles off; and the butter and skimmed milk find their way no great distance from home, as is evident by the price of butter varying frequently one-third in 20 or 30 miles. Every inhabitant of Bath must be sensible, that butter and cheese have risen one-third or more in price within 20 years. Is not this owing to the great encouragement given to the plough and to grazing, at a time when,

on account of the increased demand for milk, cream, butter, and cheese, every exertion on behalf of the dairy should have been encouraged?" &c.

In some remarks on this letter by Mr Billingsley, the same superiority of dairy-farms to the arable kind is asserted in the most positive terms. "Perhaps (says he) there cannot be a stronger proof of the inferiority of the plough with respect to profit, than the superior punctuality of the dairy-farmer in the payment of his rent. This observation, I believe, most stewards who superintend manors devoted partly to corn and partly to dairy-farms, will verify; at least I have never met with one who controverts it. But perhaps the advocate for the plough will desire me not to confound the abuse of a thing with its intrinsic excellence; and say, that the generality of corn farmers are most egregious slovens; that lands devoted to the plough are not confined to such a mediocrity of profit as 20 s. per acre; that the produce of artificial grasses (without which a well managed arable farm cannot exist), far exceeds that of natural grass both in respect of quantity and nutrition; that the straw-yard is a most convenient receptacle for the cow when freed from the pail. These, and many other reasons, may be adduced to show the propriety of walking in the middle path, and of judiciously blending *arable* with *pasture*, in the proportion perhaps of *three* of the latter to *one* of the former."

On these letters we shall only remark, that for the good of mankind we hope the opinions they contain will never come into general practice; as thus the price of bread must be raised so high, that the lower classes of people would be entirely deprived of it. In the Bath Papers, vol. v. p. 43. we have a method proposed by Mr Wimpey of improving small arable farms in such a manner as to make them yield as much milk, butter, and cheese, as those which are kept continually in pasture. He agrees with the maxim already mentioned, that small arable farms do not afford the occupier so good a maintenance as dairy farms of the same value; and that the possessor of a dairy farm will do well and save money, while the former, with much toil and trouble, is starving himself and family. Notwithstanding this, he maintains, that there is an essential difference between ground that is naturally arable, and such as is by nature adapted for pasture. Land which is naturally arable, according to him, can by no means be converted into pasture of any duration. "Such as, from a wild state of nature, over-run with furze, fern, bushes and brambles, has been rendered fertile by means of the plough, must be kept in that improved state by its frequent use; otherwise it would soon revert to that wild barren state which was its original condition. A farm, therefore, which consists wholly, or almost so, of land that is properly arable, must ever continue arable; for it is not practicable to render it in any degree fertile but by means of the plough, or to keep it long in that state even when it is made so." He is of opinion, however, that by raising crops proper for feeding cattle, the possessor of an arable farm may raise as great a number of horned cattle as one who has a pasture farm; the only question is, Whether he can be reimbursed of his expences by the produce? "To ascertain this fact

(says

(says he), we must inquire what may be the average expences of keeping a milch-cow on a dairy-farm for any given time. It is said, upon very good authority, that the expence is generally from 3 l. to 3 l. 10 s. per annum. Two acres and an half of pasture fit for this use is sufficient to keep a cow the whole year through, and such land is valued at from 25 s. to 30 s. per acre. At 25 s. the keeping of each cow would amount to 3 l. 2 s. 6 d. per annum. A dairy-farm, therefore, consisting of 48 acres, at 25 s. per annum, would amount to 60 l. rent; and the number of cows that might be kept on such a farm would be about 20. In the next place, with regard to the expence of keeping a cow upon food raised in arable land as a succedaneum for grass, we are assured by unquestionable authority, that a bushel of potatoes given half at night and half in the morning, with a small allowance of hay, is sufficient to keep three cows a-day; by which allowance their milk will be as rich and as good as in the summer months when the cows are in pasture. An acre of land, properly cultivated with potatoes, will yield 337 bushels; and the total expence of cultivation, rent and tithe included, will not exceed 6 l. 13 s. If three cows eat seven bushels per week, then they would eat 364 bushels in a year; and 20 cows would consume 2433 bushels: So that, according to this calculation, seven acres and a quarter would nearly maintain as many cows as on the arable farm could be maintained by 48 acres. If then the cultivation of one acre of ground costs 6 l. 13 s. the cultivation of seven acres and a quarter will cost about 48 l. We have seen, however, that the rent of a dairy-farm capable of maintaining 20 milch-cows, is not less than 60 l. so that the calculation is thus entirely in favour of the arable farm; seven or eight acres of the arable farm being superior by 12 l. in value, when cultivated with potatoes, to 48 acres of meadow or pasture-ground." "It must indeed be observed (adds our author), that in this statement no allowance is made for the small quantity of hay given to the cows with the potatoes. It must be noted also, that the account of cultivation is charged with 40 s. an acre for manure, and some expence for ploughing, which of right is chargeable to the crop of wheat that is to follow. Now, if we deduct 40 s. an acre from the expence of cultivating the potatoes, it reduces the sum to 4 l. 13 s. and the whole expence upon seven acres and a quarter is thus less than 34 l. and consequently the keep of 20 cows is little more than half to the occupier of the arable farm what it is to the occupier of the grazing farm. If this conclusion be fairly drawn, and the calculation free from errors, it is matter of the greatest importance, especially to the little arable farmer. It plainly raises him from a state of acknowledged inferiority to one greatly superior."

16
Objection
answered
from an
experiment
of Mr.
Vagg.

Our author next proceeds to obviate an objection, "that the whole of his reasoning must be indecisive, as relating only to potatoes." In opposition to this, he adduces an experiment made on a pretty large scale by Mr Vagg; from which it appears, that cabbages, when raised upon arable ground, are nearly as much superior to a natural crop as potatoes are. Twelve acres were employed in this experiment, and those of an indifferent quality. The rent was 30 s. per acre, and the

whole expence of culture and carting off the crop amounted only to 1 l. 14 s. so that all the cost of the twelve acres was 38 l. 9 s. From the produce were fed 45 oxen and upwards of 60 sheep; and he was assured that they improved as fast upon it as they do in the best pasture months, May, June, and July. "Now (says Mr Wimpey), if instead of 60 sheep we reckon 15 oxen, or that four sheep are equal to about one ox, in which we cannot err much; then 60 oxen were kept well for three months, or, which is the same thing, 15 for a whole year, for 38 l. 9 s.; and consequently 20 oxen would cost 5 l. 5 s. 4 d. which is not quite 3 l. more than the keeping of 20 cows would cost in potatoes. Turnips, turnip-rooted cabbage, carrots, parsnips, and some other articles, by many experiments often repeated, have been found quite adequate to the same valuable purposes; at least so far as to be more lucrative than meadow or pasture. Clover and rye-grass are omitted, as having been long in general practice; but are in common very short of the advantages which may be derived from the cultivation of the other articles recommended." Sainfoin is greatly recommended: but our author acknowledges that it makes but a miserable appearance the first year, though afterwards he is of opinion that one acre of sainfoin is equal to two of middling pasture-ground; for which reason he accuses the farmer of intolerable indolence who does not cultivate so useful a plant. On this subject, however, we must remember, that the culture of sainfoin is clogged with the loss of one if not two crops; which may sometimes be inconvenient, though afterwards it remains in perfection for no less than 20 years. The most advantageous method of raising it he supposes to be after potatoes. Thus it will thrive even upon very poor ground; as the culture and manure necessary for the potatoes both pulverise the soil and enrich it to a sufficient degree.

From these experiments and observations, therefore, it appears very probable at least, that it is by no means against the interest of a farmer to cultivate large quantities of grain; and that he may even do this in a consistency with raising as many cattle as he can have occasion for. Some grounds, no doubt, are naturally so fitted for pasture, that it would be too expensive to force them into arable ground; but wherever this can be done, it seems proper always to have as much arable as possible, instead of as little, which Messrs Davis and Billingsley advise. Grain of different kinds, therefore, and particularly wheat, ought to be cultivated by a farmer to as great an extent as possible; though these different kinds can be determined only from the nature of the soil, and certain circumstances arising from the situation of the place, for which no particular rules can be given. A view of the general practice of some of the principal counties in England, however, may perhaps be of some use to furnish general directions for the farmer.

SECT. I. Of the Cultivation of Wheat.

THERE is perhaps no part of Great Britain where this species of grain is cultivated to more perfection than in Norfolk. Mr Marshal informs us, that the species raised in that county is called the *Norfolk red*, and weighs

17
Number of
cattle fed
from 12
acres of
cabbages.

18
Great quantities of grain may be advantageously raised.

19

Wheat

weighs heavier than any other which has yet been introduced, though he owns that its appearance is much against the assertion, it being a long thin grain, resembling rye more than well bodied wheat. About 15 or 20 years ago a new species was introduced, named the *Kentish cosh*; against which the millers were at first very much prejudiced, though this prejudice is now got over. A remarkable circumstance respecting this grain is, that though upon its introduction into the county the *cosh* or husk be perfectly white, yet such is the power either of the soil or of the mode of cultivation to produce what the botanists call *varieties*, that the grain in question is said to lose every year somewhat of the whiteness of its husks, until they become at last equally red with those of the former kind. The southern and southeastern parts of the county generally enjoy a stronger and richer soil than the more northerly, and therefore are more proper for the cultivation of that species of grain. In the northern parts are some farms of very light soil, where the farmers sow only a small quantity of wheat; and these light lands are called *barley farms*.

20
Succession
of crops,
&c.

The greatest part of the wheat in Norfolk is sown upon a second year's lay; sometimes it is sown upon a first year's lay; sometimes on a summer-fallow; after peas, turnips, or buck harvested or plowed under. The practice adopted by those who are looked upon as superior husbandmen in the county of Norfolk is as follows. The second year's lays having finished the bullocks, and brought the stock-cattle and horses thro' the fore-part of summer, and the first year's lays having been made ready to receive his stock, the farmer begins to break up his old land or lay-ground by a peculiar-mode of cultivation named *rice-balking*, in which the furrow is always turned toward the unplowed ground, the edge of the coulter passing always close by the edge of the flag last turned. This is done at first with an even regular furrow; opportunity being taken for performing the operation after the surface has been moistened by a summer-shower. In this state his summer-lays remain until towards the end of harvest, when he harrows and afterwards plows them across the balks of the former plowing, bringing them now up to the full depth of the soil. On this plowing he immediately harrows the manure, and plows it in with a shallow furrow. The effects of this third plowing are to mix and effectually pulverise the soil and manure; to cut off and pulverise the upper surfaces of the furrows of the second plowing; and thus, in the most effectual manner, to eradicate or smother the weeds which had escaped the two former ones. Thus it lies until the seed-time, when it is harrowed, rolled, sown, and gathered up into ridges of such width as the farmer thinks most proper. Those of six furrows are most common, though some very good farmers lay their wheat-land into four-furrow, and others into ten-furrow ridges; "which last (says our author) they execute in a style much superior to what might be expected from wheel-plows." They excel, however, in the six-furrow plowing; of which Mr Marshal gives a particular account. When plowing in this manner, they carry very narrow furrows; so that a six-furrow ridge, set out by letting the off-horse return in the first-made furrow, does not measure more than three feet eight or nine inches.

plained.

Wheat.

When wheat is cultivated after the first year's lay, the seed is generally sown upon the flag or furrow turned over. After pease, one or two plowings are given; the other parts of the management being the same with that after the second year's lay already mentioned. After buck harvested he seldom gives more than two, and sometimes but one, plowing. In the former case he spreads his manure on the stubble, and plows it in with a shallow furrow; harrows, rolls, sows, and gathers up the soil into narrow work. The manure is in like manner spread on the stubble after once plowing, and the seed is then sown among the manure; the whole plowed in together, and the soil gathered up into narrow ridges, as if it had undergone the operations of a fallow. An inconvenience attending this practice is, that the buck which is necessarily shed in harvesting springs up among the wheat, and becomes a weed to it, at the same time that the rooks, if numerous, pull up both buck and wheat, leaving several patches quite bare. This is obviated in a great measure by first plowing in the manure and self-sown buck with a shallow furrow; in consequence of which the buck vegetates before the wheat.

It is likewise a favourite practice with the Norfolk farmers to raise wheat after buck plowed under. They plow under the buck by means of a broom made of rough bushes fixed to the fore tackle of the plow between the wheels, which bears down the plant without lifting the wheels from the ground. Sometimes, when the buck is strong, they first break it down with a roller going the same way that the plow is intended to go; afterwards a good plowman will cover it so effectually that scarce a stalk can be seen. Sometimes the surface of the ground is left rough, but it is more eligible to harrow and roll it. The practice of summer-fallowing seldom occurs in Norfolk; though sometimes, when the soil has been much worn down by cropping, and over-run by weeds, it is esteemed a judicious practice by many excellent husbandmen, and the practice seems to be daily gaining ground. After turnips the soil is plowed to a moderate depth, and the seed sown over the first plowing; but if the turnips be got in early, the weeds are sometimes first plowed in with a shallow furrow, and the seed plowed under with a second plowing, gathering the soil into narrow ridges.

With regard to the manuring of the ground for wheat in Norfolk, that which has been recently clayed or marled is supposed to need no other preparation any more than that which has received 15 or 20 loads of dung and mould for turnips; the first year's lay having been teathed in autumn, and the second fed off. Where the soil is good, and the wheat apt to run too much to straw, it is the practice of some judicious farmers to set their manure upon the young clover, thereby depriving the wheat in some degree of its rankness; but it is most common to spread it upon the broken ground; or if the seed be sown upon the turned furrow, to spread it on the turf and plow it under; or to spread it on the plowed surface, and harrow it in with the seed as a top-dressing. A smaller quantity of manure is generally made use of for wheat than for turnips. From eight to ten cart-loads (as much as three horses can conveniently draw) are reckoned sufficient for an acre; three or four

12
Manuring
the ground
in Norfolk.

Wheat. four chaldrons of lime to one acre, or 40 bushels of foot to the same quantity of ground; or about a ton of rape-cake to three acres.

²³ Time of sowing. In this county they never begin to sow wheat till after the 17th of October, and continue till the beginning of December, sometimes even till Christmas. They give as a reason for this late sowing, that the wheat treated in this manner is less apt to run to straw than when sown earlier. The seed is generally prepared with brine, and candied in the usual manner with lime. The following method of preparing it is said to be effectual in preventing the smut. "The salt is dissolved in a very small quantity of water, barely sufficient for the purpose. The lime is slaked with this solution, and the wheat candied with it in its hottest state, having been previously moistened with pure water." According to our author's observation, the crops of those farmers who use this preparation are in general more free from smut than those who make use of any other.

²⁴ Of preparing the seed. The practice of dibbling or setting of wheat has not as yet become general throughout Norfolk, the common broad-cast method being usually followed, except on the Suffolk side of the county. Some few make use of dibbling and fluting rollers; but drilling is almost entirely unknown, notwithstanding the great aptitude of soil for the practice. Plowing in the seed under furrow is the favourite mode of the Norfolk farmers, and is performed in the following manner: "The land having been harrowed down level, and the surface rendered smooth by the roller, the head-plowman (if at leisure) marks out the whole piece in narrow slips of about a statute rod in width. This he does by hanging up the plough in such a manner, that no part of it except the heel touches the ground; and this makes a sure mark for the seedsmen, which he cannot by any means mistake. In case the ploughs are all employed, the seedsmen himself marks the ground, by drawing a piece of wood or other heavy body behind him." Mr Marshall prefers this to the Kentish method of setting up sticks in the form of a lane, as being less liable to produce mistakes.

²⁵ Method of sowing. In those places where wheat is dibbled, they make use of iron instruments for the purpose. The acting part is an egg-shaped knob, somewhat larger than a pigeon's egg; the smaller end is the point of the dibble, the larger having a rod of iron rising from it about half an inch square, and two feet and an half long; the head being received into a cross piece of wood resembling the crutch of a spade or shovel, which forms the handle. The dibbler uses two of these instruments, one in each hand; and, bending over them, walks backward upon the turned furrows, making two rows of holes in each of them. These rows are usually made at the distance of four inches from each other; the holes being two and an half or three inches distant, viz. four in each length of the foot of the dibbler. The great art in making these lies in leaving them firm and smooth in the sides, so that the loose mould may not run in to fill them up before the seeds are deposited. This is done by a circular motion of the hand and wrist; making a semi-revolution every stroke; the circular motion beginning as the bit enters, and continuing until it is entirely disengaged from the mould. The operation is not

perfect unless the dibbles come out clean and wear bright. It is somewhat difficult to make the holes at equal distances; but more especially to keep the two straight and parallel to each other, some practice being required to guide the instruments in such a manner as to correspond exactly with each other; but though couples have been invented to remedy this inconvenience to keep them at a proper distance, the other method is still found to be preferable. A middling workman will make four holes in a second. One dibbler is sufficient for three droppers; whence one man and three children are called a *set*. The dibbler carries on three flags or turned furrows; going on some yards upon one of the outside furrows, and returning upon the other, after which he takes the middle one; and thus keeps his three dibblers constantly employed, and at the same time is in no danger of filling up the holes with his feet. The droppers put in two or three grains of wheat into each hole; but much time and patience is necessary to teach them to perform the business properly and quickly. An expert dibbler will hole half an acre in a day; though one third of an acre is usually reckoned a good day's work. The seed is covered by means of a bush-harrow; and from one bushel to six pecks is the usual quantity for an acre. Notwithstanding the advantages of saving seed, as well as some others which are generally reckoned undeniable, it is asserted by some very judicious farmers, that dibbling of wheat on the whole is not really a profitable practice. It is particularly said to be productive of weeds unless dibbled very thick; which indeed may probably be the case, as the weeds are thus allowed a greater space to vegetate in. Mr Marshall himself is of opinion, that "the dibbling of wheat appears to be peculiarly adapted to rich, deep soils, on which three or four pecks dibbled early may spread sufficiently for a full crop; whereas light, weak, shallow soils, which have lain two or three years, and have become grassy, require an additional quantity of seed, and consequently an addition of labour, otherwise the plants are not able to reach each other, and the grasses of course find their way up between them, by which means the crop is injured and the soil rendered foul."

²⁶ Plowing the seed under furrow described. The same author has likewise given an account of the method of cultivating wheat practised in other English counties. In the Midland district, including part of Staffordshire, Derbyshire, Warwick, and Leicestershire, we are informed that the species usually sown is that called *Red lammas*, the ordinary red wheat of the kingdom; but of late a species named the *Essex dun*, similar to the *Kentish white cosh* of Norfolk, and the *Hertfordshire brown* of Yorkshire, have been coming into vogue. Cone-wheat, formerly in use in this district, is now out of fashion. Spring wheat is cultivated with remarkable success, owing principally to the time of sowing; viz. the close of April. Our author was informed by an excellent farmer in these parts, that by sowing early, as in the beginning of March, the grain was liable to be shrivelled, and the straw to be blighted; while that which was sown towards the end of April, or even in the beginning of May, produced clean plump corn. At the time he visited this country, however, it seemed to be falling into disrepute.

²⁷ Instruments for dibbling wheat described. Objections against the practice of dibbling.

²⁸ Culture of wheat in the midland district.

Wheat.

pute; though he looks upon it, in some situations, especially in a turnip-country, to be eligible. In the ordinary succession in this part of the kingdom, wheat comes after oats; and there is perhaps nine-tenths of the wheat in this district sown upon oat-stubble. Our author has also seen a few examples of wheat being sown upon turf of six or seven year's laying; and several others on clover ley once plowed, as well as some after turnips. The best crops, however, produced in this, or perhaps in any other district, are after summer fallow. The time of sowing is the month of October, little being sown before Michaelmas; and in a favourable season, little after the close of the month. Much seed is sown here without preparation. When any is made use of, it is the common one of brine candied with lime. The produce is very great, the medium being full three quarters per acre, sometimes four or five; and one farmer, in the year 1784, had, on 50 acres of land together, no less than 45 bushels per acre.

³⁰
In the Vale
of Gloucester.

In the Vale of Gloucester, the *cone wheat*, a variety of the *triticum turgidum*, is cultivated, as well as the lammas and spring wheats. It is not, however, the true cone wheat which is cultivated here, the ears being nearly cylindrical; but our author met with the true species in North-Wiltshire. Beans in this country are the common predecessors of wheat, and sometimes pease; but here the farmers cultivate wheat upon every species of soil. The time of sowing is in November and December, and the seed is thought to be sown in sufficient time if it is done before Christmas. In this country it is thought that late sown crops always produce better than those which are sown early; but Mr Marshall accounts for this by the vast quantity of weeds the latter have to encounter, and which the late sown crops escape by reason of the weakness of vegetation at that time of the year. The produce, however, throughout the Vale of Gloucester, is but very indifferent.—Setting of wheat is not practised, but hoeing universally.—In harvesting, Mr Marshall observes, that the grain is allowed to stand until it be unreasonably ripe, and that it is bound up into very small sheaves. The practice of making double bands is unknown in this district; so that the sheaves are no bigger than can be contained in the length of single straw. The inconveniences of this method are, that the crop requires more time to stook, load and unload, and stack: the advantages are, that the trouble of making bands is avoided; and that if rainy weather happens to intervene, the small sheaves dry much sooner than the large ones. Here the crop is cut very high, the stubble and weeds being mown off in swaths for litter soon after the crop is cut; and sometimes sold as high as 5s. per acre.—Mr Marshall is at a loss to account for the little quantity produced in this country; it being hardly possible to derive it from the nature of the soil, almost all of it being proper for the cultivation of the grain.

³¹
Remarkably small
sheaves.

³²
In the Cotswold hills.

Among the Cotswold hills of Gloucester the lammas and cone wheats are sown; and a new variety of the latter was raised not long ago by picking out a single grain of seed from among a parcel. The body is very long and large, but not slightly.—The Cotswold hills are almost proverbial for early sowing of wheat. The general rule is to begin plowing in July, and sowing the first wet weather in August; so that here

N^o 159.

the seed-time and harvest of wheat coincide. If in consequence of this early sowing the blade becomes rank in autumn, it is supposed to be proper to eat it down by putting a large flock of sheep upon it at once. Eating it in spring is considered as pernicious. It is usually weeded with spud-hooks; not hoed, as in the Vale. One instance, however, is mentioned by our author, in which a very thin crop full of seed-weeds was hoed in autumn with uncommon success, occurred in the practice of a superior manager in this district; as well as others in which wheat has been weeded in autumn with great advantage. He also met with another well authenticated instance of the good effect of cutting mildewed wheat while very green. “A fine piece of wheat being lodged by heavy rains, and being soon after perceived to be infected with the mildew, was cut, though still in a perfectly green state: namely, about three weeks before the usual time of cutting. It lay spread abroad upon the stubble until it became dry enough to prevent its caking in the sheaf; when it was bound and set up in shocks. The result of this treatment was, that the grain, though small, was of a fine colour, and the heaviest wheat which grew upon the same farm that season; owing, no doubt, to the thinness of its skin. What appears much more remarkable, the straw was perfectly bright, not a speck upon it.—In this part of the country, the produce of wheat is superior to that in the Vale; but Mr Marshall is of opinion, that the soil is much more fit for barley than wheat.

In Yorkshire, though generally a grass-land country, and where of consequence corn is only a secondary concern, yet several kinds of wheat are cultivated, particularly *Zealand*, *Downy Kent*, *Common White*, *Hertsfordshire Brown*, *Yellow Kent*, *Common Red*. All these are varieties of winter wheat; besides which they cultivate also the *spring* or *summer wheat*. Here our author makes several curious observations concerning the raising of varieties of plants. “It is probable (says he), that time has the same effect upon the varieties of wheat and other grains as it has on those of cultivated fruits, potatoes, and other vegetable productions. Thus, to produce an early pea, the garden ermarks the plants which open first into blossom among the most early kind he has in cultivation. Next year he sows the produce of those plants, and goes over the coming crop in the manner he had done the preceding year, marking the earlier of this early kind. In a similar manner new varieties of apples are raised, by choosing the broadest leaved plants among a bed of seedlings rising promiscuously from pippins. Husbandmen, it is probable, have heretofore been equally industrious in producing fresh varieties of corn; or whence the endless variety of winter wheats? If they be naturally of one species, as Linnæus has deemed them, they must have been produced by climature, soil, or industry; for although nature sports with individuals, the industry of man is requisite to raise, establish, and continue a permanent variety. The only instance in which I have had an opportunity of tracing the variety down to the parent individual, has occurred to me in this district.—A man of acute observation, having, in a piece of wheat, perceived a plant of uncommon strength and luxuriance, diffusing its branches on every side, and setting its closely-surrounding neighbours

³⁵

³⁶
Observations on raising
varieties of
plants.

Wheat.

bours at defiance; marked it, and at harvest removed it separately. The produce was 15 ears, yielding 604 grains of a strong-bodied liver-coloured wheat, different, in general appearance, from every other variety he had seen. The chaff was smooth, without awns, and of the colour of the grain; the straw stout and reedy. These 604 grains were planted singly, nine inches asunder, filling about 40 square yards of ground, on a clover stubble, the remainder of the ground being sown with wheat in the ordinary way; by which means extraordinary trouble and destruction by birds were avoided. The produce was two gallons and an half, weighing 20½ lb. of prime grain for seed, besides some pounds of seconds. One grain produced 35 ears, yielding 1235 grains; so that the second years produce was sufficient to plant an acre of ground.—What deters farmers from improvements of this nature is probably the mischievousness of birds; from which at harvest it is scarcely possible to preserve a small patch of corn, especially in a garden or other ground situated near an habitation; but by carrying on the improvement in a field of corn of the same nature, that inconvenience is got rid of. In this situation, however, the botanist will be apprehensive of danger from the floral farina of the surrounding crop. But from what observations I have made, I am of opinion his fears will be groundless. No evil of this kind occurred, though the cultivation of the above variety was carried on among *white* wheat. But this need not be brought as an evidence: it is not uncommon here to sow a mixture of red and white wheats together; and this, it is confidently asserted, without impairing even the colour of either of them. The same mode of culture is applicable to the improvement of varieties; which perhaps would be more profitable to the husbandman than raising new ones, and more expeditious.”

37
Preparation
of wheat
with arsenic.

In Yorkshire a very singular preparation of seed-wheat prevails, viz. the steeping it in a solution of *arsenic*, as a preventative of smut. Marshall was informed by one farmer, that he had made use of this preparation for 20 years with success, having never during that long space of time suffered any sensible injury from smut. Our author seems inclined to believe the efficacy of this preparation; but thinks there may be some reason to apprehend danger in the use of such a pernicious mineral, either through the carelessness of servants, or handling of the seed by the person who sows it. The farmer above mentioned, however, during all the time he used it, never experienced any inconvenience either to himself, the seedman, or even to the poultry; though these last, we should have thought, would have been peculiarly liable to accidents from arsenicated seed.—The preparation is made by pounding the arsenic extremely fine, boiling it in water, and drenching the seed with the decoction. “In strictness (says Mr Marshall), the arsenic should be levigated sufficiently fine, to be taken up and washed over with water, reducing the sediment until it be fine enough to be carried over in the same manner.—The usual method of preparing the liquor is to boil one ounce of white arsenic, finely powdered, in a gallon of water, from one to two hours; and to add to the decoction as much water or stale urine as will increase the liquor to two gallons.—In this liquor the seed is, or ought to be, immersed, stirring it about in such a

VOL. VIII. Part II.

manner as to saturate effectually the downy end of each grain.—This done, and the liquor drawn off, the seed is considered as fit for the seed-basket, without being candied with lime, or any other preparation.—A bushel of wheat has been observed to take up about a gallon of liquor. The price of arsenic is about 6d. per pound; which on this calculation will cure four quarters of seed. If no more than three quarters be prepared with it, the cost will be only a farthing per bushel; but to this must be added the labour of pounding and boiling. Nevertheless, it is by much the cheapest, and perhaps, upon the whole (adds Mr Marshall), the best preparation we are at present acquainted with.—In this county it is believed that a mixture of wheat and rye, formerly a very common crop in these parts, is never affected with mildew; but our author does not vouch for the truth of this assertion.

Barley.

SECT. II. Barley.

THE county of Norfolk, according to Mr Marshall, ³⁸ is peculiarly adapted to the cultivation of this grain, of barley in the strongest soil not being too heavy, and the lightest ³⁸ Norfolk. being able to bear it; and so well versed are the Norfolk farmers in the cultivation of it, that the barley of this county is desired for seed throughout the whole kingdom.—It is here sown after wheat or turnips; and in some very light lands it is sown after the second year's lay.—After wheat, the seed-time of the latter being finished, and the stubble trampled down with bullocks, the land is ploughed with a shallow furrow for a winter-fallow for barley. In the beginning of March the land is harrowed and cross-ploughed; or if it be wet, the ridges are reversed. In April it receives another ploughing lengthways; and at seed-time it is harrowed, rolled, sowed, and the surface rendered as smooth and level as possible.—After turnips the soil is broken up as fast as the turnips are taken off; if early in winter by *rice balking*, a practice already explained*; but if ^{See n° 224.} late, by a plain plowing. It is common, if time will permit, to plough three times; the first shallow, the second full, and the third a mean depth; with which last the seed is plowed in. Sometimes, however, the ground is ploughed only once, and the seed sown above; but more frequently by three ploughings, though perhaps the farmer has not above a week to perform them in.—After lay, the turf is generally broken by a winter fallow, and the soil treated as after wheat.

This grain is seldom manured for, except when sown after lay, when it is treated as wheat. No manure is requisite after turnips or wheat, if the latter has been manured for. If not, the turnip-crop following immediately, the barley is left to take its chance, unless the opportunity be embraced for winter-marling.

Little barley is sown by the Norfolk farmers before the middle of April, and the seed-time generally continues till the middle of May; though this must in some measure depend on the season; “which (says Mr Marshall) is more attended to in Norfolk than perhaps in all the world beside.” In the very backward spring of 1782, barley was sown in June with success. No preparation is used. It is all sown broad-cast, and almost all under furrow; that is, the surface having been smoothed by the harrow and roller, the seed is

5 A

sown

Barley.

sown and plowed under with a shallow furrow; but if the season be wet, and the soil cold and heavy, it is sometimes sown above; but if the spring be forward, and the last piece of turnips eaten off late, the ground is sometimes obliged to be plowed only once, and to be sown above; though in this case Mr Marshall thinks it the most eligible management, instead of turning over the whole thickness of the soil, to *two-furrow* it, and sow between. This is done by only skimming the surface with the first plough, sowing the seed upon this, and then covering it with the bottom-furrow brought up by the second plough. Three bushels are usually sufficient for an acre.

The barley, as well as the wheat, in Norfolk, is allowed to stand till very ripe. It is universally mown into swath, with a small bow fixed at the heel of the scythe. If it receive wet in the swath in this country, it is not turned, but *lifted*; that is, the heads or ears are raised from the ground, either with a fork or the teeth of a rake, thereby admitting the air underneath the swaths; which will not fall down again to the ground so close as before, so that the air has free access to the under side: and this method of lifting is supposed not to be inferior to that of turning, which requires more labour, besides breaking and ruffling the swaths.

³⁹
In the Vale
of Gloucester.

In the Vale of Gloucester the quantity of barley cultivated is very inconsiderable; the only species is the common long-eared barley, *hordeum zeocriton*. In this county the grain we speak of is used, on the every year's lands, as a cleansing crop. It is sown very late, *viz.* in the middle or end of May; sometimes the beginning or even the middle of June. The reason of this is, that the people of the Vale think, that if a week or ten days of fine weather can be had for the operation of harrowing out couch, and if after this a full crop of barley succeed, especially if it should fortunately take a reclining posture, the business of fallowing is effectually done, inasmuch that the soil is cleaned to a sufficient degree to last for a number of years. A great quantity of seed is made use of, *viz.* from three to four bushels to an acre; under the idea, that a full crop of barley, especially if it lodge, smother all kinds of weeds, couch-grass itself not excepted. Our author acknowledges this effect in some degree, but does not recommend the practice. "If the land (says he) be tolerably clean, and the season favourable, a barley fallow may no doubt be of essential service. But there is not one year in five in which even land which is tolerably clean can be sown in season, and at the same time be much benefited by it for future crops." The barley in this county is all hand-weeded. It is harvested loose, mown with the naked scythe, lies in swath till the day of carrying, and is cocked with common hay forks. The medium produce is three quarters per acre. Its quality is preferable to that of the hill-barley.

⁴⁰
In Cotswold.

The common long-eared species is sown among the Cotswold hills. It is sown in the latter end of March and beginning of April, in the quantity of three bushels to an acre, producing from 20 bushels to four quarters to an acre; "which (says our author) is a low produce. It must be observed, however, that this produce is from land deficient in tillage; and that barley delights in a fine pulverous tilth."

Barley.

In the Midland district they cultivate two species of barley, *viz.* the *zeocriton* or common long eared, and the *distichon* or sprat barley; the latter not being of more than 50 years standing, but the former of much older date. The sprat is the more hardy, and requires to be more early sown; but the long-ear yields the better produce. It succeeds wheat and turnips; but on the strong lands of this district, the crop after wheat is much less productive, as well as less certain, than after turnips; which circumstance is likewise observed in Norfolk. It is sometimes also sown with success upon turf. When sown after wheat, the soil is winter-fallowed by three ploughings; the first lengthways in November; the second across in March; the last, which is the seed-plowing, lengthways. Between the two last ploughings the soil is harrowed, and the twitch shaken out with forks; after which it is left loose and light to die upon the surface, without being either burnt or carried off. After turnips the soil has commonly three ploughings; the reason of which is, that the turnips being commonly folded off with sheep, the soil, naturally of a close texture, receives a still greater degree of compactness, which it is proper to break down, and render it porous. The seed-time is the two last weeks of April and the first of May; from two bushels and a half to three bushels an acre, sometimes even as much as four bushels; the produce very great, sometimes as high as seven or even eight quarters an acre; but the medium may be reckoned from four to four and an half quarters. Mr Marshall remarks, that the culture of barley is extremely difficult. "Something (says he) depends on the nature of the soil, much on the preparation, much on the season of sowing, and much on harvesting. Upon the whole, it may be deemed, of corn-crops, the most difficult to be cultivated with certainty."

⁴²
Culture of
barley difficult.

In Yorkshire there are four kinds of barley cultivated, *viz.* the *zeocriton* or long-eared; the *distichon* or sprat; the *vulgare*, big, four-rowed or spring-barley; and the *hexastichon*, six-rowed or spring-barley. The first and third sorts are principally cultivated; the winter-barley is as yet new to the district. Battledoor-barley was formerly very common, but is now almost entirely disused. Mr Marshall observes, that less than a century ago, barley was not saleable until it was malted; there were neither maltsters nor public houses, but every farmer malted his own grain, or sold it to a neighbour who had a malt-kiln. Brakes cut from the neighbouring commons were the fuel commonly used upon this occasion, and a certain day for cutting them was fixed, in order to prevent any one from taking more than his share. The case is now totally reversed; even public malt-houses being unknown, and the business of malting entirely performed by maltsters, who buy the barley from the farmer, and sell him what malt he may want for his family.

⁴³
In Yorkshire.

SECT. III. Oats.

In Norfolk this kind of grain is much less cultivated than barley; and the only species observed by Mr Marshall is a kind of white oat, which grows quickly, and seems to be of Dutch extraction. They are cultivated occasionally on all kinds of soils; but more especially on cold heavy land, or on very light, unproductive,

⁴⁴
Norfolk
cultivation of
oats.

⁴⁵ ^{Oats.} ductive, heathy, soils. They most frequently succeed wheat or lay-ground barley: "but (says our author) there are no established rules respecting any part of the culture of this time-serving crop." The culture of the ground is usually the same with that of barley; the ground generally undergoing a winter fallow of three or four ploughings, though sometimes they are sown after one ploughing. They are more commonly sown above furrow than barley. The seed-time is made subservient to that of barley, being sometimes sooner and sometimes later than barley seed-time: and Mr Marshall observes, that he has sometimes seen them sown in June; it being observable, that oats sown late ripen earlier than barley sown at the same time. The quantity of seed in Norfolk is from four to five bushels per acre; but he does not acquaint us with the produce. He mentions a very singular method of culture sometimes practised in this county, viz. ploughing down the oats after they begin to vegetate, but before they have got above ground; which is attended with great success, even though the ground is turned over with a full furrow. By this method weeds of every kind are destroyed, or at least checked in such a manner as to give the crop an opportunity of getting above them; and the porosity communicated to the soil is excellently well adapted to the infant-plants of barley; which probably might frequently receive benefit from this operation.

⁴⁶ ^{Wild oats} In the Vale of Gloucester, Mr Marshall observes, that the wild oat is a very troublesome weed, as well as in Yorkshire; and he is of opinion, that it is as truly a native of Great Britain as any other arable weed, and is perhaps the most difficult to be extirpated. It will lie a century in the soil without losing its vegetative quality. Ground which has lain in a state of grass time immemorial, both in Gloucester and Yorkshire, has produced it in abundance on being broken up. It is also endowed with the same seemingly instinctive choice of seasons and state of the soil as other seeds of weeds appear to have. Hence it is excessively difficult to be overcome; for as it ripens before any crop of grain, it sheds its seed on the soil, where the roughness of its coat probably secures it from birds. The only methods of extirpating this plant are fallowing, hoeing, and handweeding, where the last is practicable, after it has shot its panicle.

⁴⁷ ^{Oats not} No oats are cultivated in the Vale of Gloucester; though the wild oat grows every where as already said. Mr Marshall is of opinion that it is better adapted to oats than to barley. The reason he assigns for the preference given to the latter is, that in this part of the country the monks were formerly very numerous, who probably preferred ale to oaten cake.—He now, however, recommends a trial of the grain on the stronger cold lands in the area of the Vale, as they seldom can be got sufficiently fine for barley. The fodder from oats he accounts much more valuable than that from barley to a dairy country; and the grain would more than balance in quantity the comparative difference in price.

⁴⁸ ^{Cultivation} In the midland district the *Poland oat*, which was formerly in vogue, has now given place to the *Dutch* or *Friezeland* kind. It is constantly sown after turf; one ploughing being given in February, March, or April. The seed-time is the latter end of March and begin-

ning of April, from four to seven bushels an acre; the produce is in proportion to the seed, the medium being about six quarters.

In Yorkshire the Friezeland oats are likewise preferred to the Poland, as affording more straw, and being thinner skinned than the latter. The *Siberian*, or *Tartarian* oat, a species unnoticed by Linnæus, is likewise cultivated in this country: the *reed* oat is known, but has not yet come into any great estimation. The grain is light, and the straw too ready to be affected by cattle.

Oats are particularly cultivated in the western division of the Vale of Yorkshire; where the soil is chiefly a rich sandy loam, unproductive of wheat. Five or six bushels, or even a quarter of oats, are sometimes sown upon an acre; the produce from seven to ten quarters.—In this country they are threshed in the open air, and frequently even upon the bare ground, without even the ceremony of interposing a cloth. The reasons assigned for this seemingly strange practice are, that if pigs and poultry be employed to eat up the grain which escapes the broom, there will be little or no waste. Here the market is always very great for new oats, the manufacturing parts of West Yorkshire using principally oat-bread. The only objection to this practice is the chance of bad weather; but there is always plenty of straw to cover up the threshed corn, and it is found that a little rain upon the straw does not make it less agreeable to cattle.

In an experiment made by Mr Bartley near Bristol, ^{Bath Pa-} upon black oats, we are informed that he had the prodigious increase of 98½ Winchester bushels from four ^{pers, vol. iv. p. 281.} on the acre: the land was a deep, mellow, sandy loam. It had carried potatoes the former year, and received one ploughing for a winter fallow. Another ploughing was given it in February, and the seed was sown on the 27th and 28th of the month. The success of the experiment was supposed to be owing partly to the early sowing and partly to a good deep tillage.

SECT. IV. Pease.

In the Bath Papers, vol. i. p. 148. we have an account of the success of an experiment by Mr Pavier near Taunton, on sowing pease in drills, a method mentioned under the article AGRICULTURE, n° 150. The scale on which this experiment was made, however, being so small, it would perhaps be rash to infer from it what might be the event of planting a large piece of ground in the same manner. The space was only 16 square yards, but the produce so great, that by calculating from it, a statute acre would yield 600, or at the least 500 pecks of green pease at the first gathering; which, at the high price they bore at that time in the county about Taunton, viz. 16d. per peck, would have amounted to 33l. 6s. 8d. On this the Society observe, that though they doubt not the truth of the calculation, they are of opinion, that such a quantity as 500 or 600 pecks of green pease would immediately reduce the price in any country market. "If the above-mentioned crop (say they) were sold only at nine pence per peck, the farmer would be well paid for his trouble." In a letter on the drill husbandry by Mr Whitmore, for which the thanks of the Society were returned, he informs us, that drilled pease must

shall's ob-
servations.

not be sown too thin, or they will always be foul; and in an experiment of this kind, notwithstanding careful hoeing, they turned out so foul, that the produce was only eight bushels to the acre.—From an experiment related in the 5th volume of the same work, it appears that pease, however meliorating they may be to the ground at first, will at the last totally exhaust it, at least with regard to themselves. In this experiment they were sown on the same spot for ten years running. After the first two years the crop became gradually less and less, until at last the seed would not vegetate, but became putrid. Strawberries were then planted without any manure, and yielded an excellent crop.

On the Norfolk culture of pease*, Mr Marshall makes two observations. "Lays are seldom ploughed more than once for pease; and the seed is in general dibbled in upon the flag of this one ploughing. But stubbles are in general broken by a winter fallow of three or four ploughings; the seed being sown broadcast, and ploughed in about three inches deep with the last ploughing."—In the Vale of Gloucester they are planted by women, and hoed by women and children, once, twice, and sometimes thrice; which gives the crop, when the soil is sufficiently free from root-weeds, the appearance of a garden in the summer time, and produces a plentiful crop in harvest. The distance between the rows varies from 10 to 14 inches, but 12 may be considered as the medium; the distance in the rows two inches. In the Cheltenham quarter of the district, they set the peas not in continued lines, but in clumps; making the holes eight or ten inches distant from one another, putting a number of pease into each hole. Thus the hoe has undoubtedly greater freedom; all the disadvantage is, that in this case the soil is not so evenly and fully occupied by the roots as when they are disposed in continued lines.—In Yorkshire it is common to sow beans and grey pease together, under the name of *blendings*; and sometimes fitches (probably, says Mr Marshall, a gigantic variety of the *ervum lens*) are sown among beans. Such mixtures are found to augment the crop, and the different species are easily separated by the sieve.

These are the most remarkable particulars concerning the culture of corn not taken notice of under AGRICULTURE: but besides that kind of vegetables called GRAIN, there is a number of others very important both for the use of men and cattle, of which we must now treat particularly.

SECT. V. Potatoes.

THESE, next to the different kinds of grain, may be looked upon as the crop most generally useful for the husbandman; affording not only a most excellent food for cattle, but for the human species also; and are perhaps the only substitute that could be used for bread with any probability of success. In the answer by Dr Tissot to M. Linguet already mentioned, the former objects to the constant use of them as food; not because they are pernicious to the body, but because they hurt the faculties of the mind. He owns, that those who eat maize, potatoes, or even millet, may grow tall and acquire a large size; but doubts if any such ever produced a literary work of merit. It does not, however, by any means appear, that the very ge-

55
Are not
prejudicial
to man-
kind.

neral use of potatoes in our own country has at all impaired either the health of body or vigour of mind of its inhabitants. The question then, as they have already been shown to be an excellent food for cattle, comes to be merely with regard to the profit of cultivating them; and this seems already to be so well determined by innumerable experiments, as well as by the general practice of the country, that no room appears left for doubt. In the Transactions of the Society for the encouragement of Arts, a number of experiments are related by Mr Young on that kind called the *clustered* or *hog potato*, which he strongly recommends as food for the poor, in preference to the kidney or other more expensive kinds. The following is the result of the most remarkable of his experiments.

In the first week of March 1780, two acres and a quarter of barley stubble were sown with the cluster potatoe, which appeared on the 23d of May. A sharp frost on the 7th of June turned them as black as they usually are by the frosts of November and December. In time, however, they recovered; and by the end of October produced 876 bushels from the $2\frac{1}{4}$ acres; which, when cleaned, were reduced to 780, or 350 bushels per acre; thus affording, when valued only at 6d. per bushel, a clear profit of 7 l. 14s. 4d. per acre. The experiment, however, in his opinion, would have been still more profitable, had it not been for the following circumstances. 1. The soil was not altogether proper. 2. The crop was grievously injured by the frost already mentioned, which, in our author's opinion, retarded the growth for about six weeks. 3. The dung was not of his own raising, but purchased; which cannot but be supposed to make a great difference, not only on account of the price, but likewise of the quality, as happened to be the case at present. He is of opinion, however, that potatoes, at least this kind of them, are an exhausting crop. Having sown the field after this large crop of potatoes with wheat, his neighbours were of opinion that it would be too rank; but so far was this from being the case, that the wheat showed not the least sign of luxuriance, nor the least superiority over the parts adjacent which were sown without dung. He was willing to account for this by the poverty of the dung, and the severe cropping which the ground had undergone while in the possession of the former tenant. In another experiment, however, in which the ground had been likewise exhausted by severe cropping, the succeeding crop of wheat showed no luxuriance; so that the former suspicion of the exhausting quality of the cluster-potato was rather confirmed. The ground was a fine turnip loam; but though the produce was even greater than in the former case, viz. 356 bushels from an acre, the profit was much less, viz. only 4 l. 15s. 6d. An acre of ley-ground was sown at the same time with the turnip-loam, but the produce from it was only 200 bushels. Mr Young supposes that the produce would have been greater if the potatoes had been planted with an iron dibble, as the turf, in ploughing, lay too heavy upon the seed. A few rows of other potatoes, planted along with the clustered kind, did not vegetate at all; which shows that the latter have a more powerful vegetative faculty.

Having succeeded so well with his experiments on this kind of potato hitherto, Mr Young determined to try scale.

try the culture of them upon a larger scale; and therefore, in the year 1782, sowed 11 acres: but being obliged to commit the care of sowing them to an ignorant labourer, his unskilfulness, together with the excessive cold and moisture of that season, so diminished the produce, that he had only a single acre out of the whole. This produced 180 bushels, which yielded of clear profit 4 l. 2s. 6d. From this experiment he draws the following conclusions: 1. "That the poor loam, on which these potatoes were sown, will yield a crop of cluster-potatoes, though not of any other kind. 2. That the manure for potatoes ought to be carted and spread upon all soils inclinable to wet before the planting season, either in autumn preceding, or else during a hard frost." In 1783 he succeeded still worse; for having that year sown three acres and a half, the profit did not exceed 11s. 4d. per acre. The produce was about 224 bushels per acre. He gives two reasons for the failure of this crop: 1. The clustered-potato thrives best in wet years; but the summer of 1783 was dry and hot. 2. The spring frost, by interrupting the hoeing, not only greatly raised the expences, but very much injured the crop by encouraging the growth of weeds. Barley was sown after the last crop, and produced well: so that our author thinks the potatoes seem to be a better preparation for spring corn than wheat. His experiment in 1784 produced a clear profit of 2 l. 0s. 4d.; the produce being 250 bushels per acre. Still, however, an error was committed, by employing an old man and woman to cut the sets; by whose unskilfulness there were many great gaps among the potatoes as they came up; so that, on the whole, he reckons that he thus lost from 500 to 800 bushels. On the whole, however, his opinion is favourable to the cluster-potato. "With small crops (says he), and at the low rate of value which is produced by consuming them at home, they are clearly proved to be a crop which will pay the expence of manuring, and very ample tillage and hoeing. This is, after all, the chief object of modern husbandry; for if a man can rely upon this potato for the winter consumption of his yard in fattening or keeping hogs, in feeding his horses, and fattening his bullocks, he has made one of the greatest acquisitions that can be desired; since he can do all this upon land much too stiff and wet for turnips; houses his crops before the winter rains come on; and consequently without doing any of that injury to his land which the turnip culture is known to entail, and from which even cabbages are not free. Those who know the importance of winter-food on a turnip farm, cannot but admit the magnitude of this object on wet soils."

shall's re-
marks.

60
On the
curl.

Mr Marshall, in his Rural Economy of Yorkshire, has several very interesting remarks on the potato. Its varieties, he says, are endless and transitory. The rough-skinned Russia potato, which was long a favourite of the Yorkshire farmers, he is of opinion, has now no longer an existence more than many others which flourished for a time. "There is some reason to believe (says he) that the disease which has of late years been fatal to the potato-crop in this and in other districts, under the name of CURLED TOPS, has arisen from too long a continuance of declining varieties. Be this as it may, it appears to be an established opinion here, that *fresh varieties*, raised from seed, are not liable

to that disease." Our author, however, does not look upon this to be a fact absolutely established; though one instance fell under his observation, in which its removal was in all probability owing to the introduction of new varieties. It made its appearance between 40 and 50 years ago, and spread in some degree over the whole kingdom. In some places it continued but a short time, so that its effects are almost forgotten. It is seldom obvious at the first coming up of the plant, but attacks them as they increase in size; the entire top becoming dwarfish and shrivelled as if affected by drought or loaded with insects: they nevertheless live and increase, though slowly, in size; but the roots are unproductive. Some crops have been almost wholly destroyed by this disease. In Yorkshire the Morelands are in a manner free from it, but the Vale is in some measure infected. Plants procured from the Morelands remain free from it in the Vale the first year; but, being continued, become liable to the disease. Where the attack has been partial, weeding out the diseased plants as they failed, is said to have had a good effect; and it is said the Morelanders got rid of the disease by this means.

In Yorkshire, some intelligent husbandmen are acquainted with the method of raising potatoes from seed; which is as follows. "In autumn, when the apples are beginning to fall spontaneously, they are gathered by hand, and preserved among sand until the spring, when they are mashed among the sand or among fresh mould; separating the seeds and mixing them evenly with the mould. As soon as the spring frosts are judged to be over, they are sown in fine garden mould; and as fast as the plants get into rough leaf, and are strong enough to be handled without injury, they are transplanted into another bed of rich mould in rows, which are kept clean during summer. In autumn, bunches of small potatoes are found at the roots of these plants; varying in size, the first year from an hazel-nut to that of a crab. These being planted next spring, produce potatoes of the middle size; but they do not arrive at their fullest bulk until the third or fourth year. Where the use of the stove or the garden frame can be had, this process may be shortened. The seeds being sown within either of these early in the spring, the plants will be fit to be planted out as soon as the frosts are gone; by which means the size of the roots will be much increased the first year, and will in the second rise early to perfection."

61
Method of
raising va-
rieties from
seed.

In the 4th volume of the Bath Papers, Dr Anderson relates some experiments made on potatoes raised from seed. The first year they were of different sizes, from a pigeon's egg to that of a small pea. On planting these next year, it was invariably found, that the largest potatoes yielded the largest crop; and the same happened the third, when a few showed blossom; but not even these had bulbs equal to what would have been produced by very large potatoes. Whence he concludes, that it is impossible to assign any time in which these seedling potatoes will arrive at what is called *perfection*; but that it must depend very much on the nature of the soil and the culture bestowed upon them. From the practice of the Yorkshire farmers, however, and even from the experiments of the Doctor himself, it is evident, that potatoes raised in
this.

62
Dr Anderson's ex-
periments.

Potatoes.
63
Whether
potatoes de-
generate

this way will at last grow to the usual size, as during the three years in which his experiments were continued they constantly increased in bulk. Dr Anderson likewise contends, that there is no reason for supposing that potatoes raised from bulbs in the ordinary way degenerate, or require to be renewed by seminal varieties; and he instances the universal practice of Britain and Ireland for a great number of years past. But this may be accounted for from an observation of Mr Marshall's, that varieties of potatoes, like those of corn, are partial to particular soils and situations. Hence, by transplanting all the different varieties of potatoes into all possible soils and situations, as has been done within this last century in the islands of Britain and Ireland, these varieties have continued for a much longer time than they would otherwise have done. In Yorkshire, Mr Marshall tells us, that "the old favourite sorts were driven until some of the individual plants barely produced their seed again." It is evident, therefore, that there is a necessity from time to time of renewing them from seed; though it deserves well to be considered whether it would not be more eligible to choose the seed from a plant in full vigour than from that which is so far degenerated that it can scarce produce its seed. "Potatoes raised from seed (says Mr Marshall) are a miscellany of endless varieties. Sometimes these varieties are planted miscellaneously; sometimes particular varieties are selected. In selecting varieties from seedling potatoes, two things are to be attended to; the intrinsic quality of the potato, and its productiveness. If these two desirable properties can be found in one plant, the choice is determined. To this species of attention and industry we are indebted for the many valuable kinds which have been and now are distributed throughout the island. It is observable, however, that varieties of potatoes, like those of corn, are partial to particular soils and situations. Hence the propriety of husbandmen raising potatoes from seed; as by this means they obtain, with a degree of moral certainty, a sort adapted to their own particular soils and situations. Whoever has attended closely to the work of taking up potatoes, must have observed the great inequality in the productiveness of individual plants. The difference in the produce of adjoining roots, where no disparity of soil can influence, will sometimes be three or four fold. Hence it is evident, that each variety has its *sub-varieties*; through whose means it can hardly be doubted the parent variety may be improved, and its continuance be prolonged. Thus the farmer has another mean in his power of improving the quality and productiveness of his potatoe-crop, by improving varieties; or, in other words, selecting sub-varieties, superiorly adapted to his soil and situation."

With regard to the proper mode of cultivating this valuable root, it is so fully explained under the article AGRICULTURE, n^o 158 *et seq.* that nothing farther seems requisite to be said upon it in this place. We shall therefore proceed to

SECT. VI. Of Carrots.

THESE have been greatly recommended as food for cattle, and in this respect bid fair to rival the potato; though, with regard to the human species, they are far

inferior. The profit attending the cultivation of them, however, appears to be much more doubtful than that of potatoes. Mr Arthur Young informs us, that from *Norden's Surveyor's Dialogue*, published in 1600, it appears, that carrots were commonly cultivated at that time about Orford in Suffolk, and Norwich in Norfolk; and he remarks, that the tract of land between Orford, Woodbridge, and Saxmundam, has probably more carrots in it than all the rest of the kingdom put together." In 1779, few farmers in these parts had less than five or six acres; many from 10 to 20; and one had 36 acres: the straight, handsome, and clean roots were sent at 6d. *per* bushel to London; the rest being used at home, principally as food for horses. In other counties, he observes, the culture of carrots has not extended itself; that some have begun to cultivate them in place of turnips, but have soon desisted; so that the culture seems in a manner still confined to the angle of Suffolk, where it first began. In attempting to investigate the cause of this general neglect, he observes, that "the charge of cultivation is not so great as is commonly imagined, when managed with an eye to an extensive culture, and not a confined one for one or two particular objects." Two acres which our author had in carrots cost L. 3 : 17 : 6 *per* acre, including every expence; but had not the summer been dry, he observes, that his expences might have been much higher; and when he tried the experiment 15 years before, his expences, through inadvertence, ran much higher. His difficulty this year arose chiefly from the *polygonum aviculare*, the predominant weed, which is so tough that scarcely any hoe can cut it. Some acres of turnips which he cultivated along with the carrots were all eaten by the fly; but had they succeeded, the expence of the crop would have been 18s. 5d. less *per* acre than the carrots. "But (adds our author) if we call the superiority of expence 20s. an acre, I believe we shall be very near the truth: and it must at once be apparent that the expence of 20s. *per* acre cannot be the cause of the culture spreading so little; for, to answer this expence, there are favourable circumstances, which must not be forgotten. 1. They (the carrots) are much more impenetrable to frost, which frequently destroys turnips. 2. They are not subject to the distempers and accidents which frequently affect turnips; and they are sown at a season when they cannot be affected by drought, which frequently also destroys turnips. 3. They last to April, when stock, and especially sheep-farmers are so distressed, that they know not what resource to provide. 4. The culture requisite for turnips on a sandy soil, in order to destroy the weeds, destroys also its tenacity, so that the crop cannot thrive; but with carrots the case is otherwise.—Hence it appears, that the reason why the cultivation of carrots is still so limited, does not arise from the expence, but because the value is not ascertained. In places where these roots can be sent to London, or sold at a good price, the tops being used as food for cattle, there is not the least doubt that they are profitable; and therefore in such places they are generally cultivated: but from the experiments as yet laid before the public, a satisfactory decisive knowledge of the value is not to be gained. The most considerable practice, and the only one of common farmers upon a large scale, is that of the sands of Woodbridge: but here they have the benefit of a London market, as

Difficulty
of ascertain-
ing the va-
lue.

Carrots. already mentioned. Amongst those whose experiments are published, Mr Billingsley ranks foremost. Here again the value of carrots is rather depreciated than advanced; for he raised great crops, had repeated experience upon a large scale of their excellence in fattening oxen and sheep; feeding cows, horses, and hogs; and keeping ewes and lambs in a very superior manner, late in the spring, after turnips were gone: but notwithstanding these great advantages, he gave the culture up; from which we may conclude a deficiency in value. "In several experiments (though not altogether determinate), I found the value, upon an average of all applications, to be 13d. a bushel, heaped measure; estimating which at 70 lb. weight, the ton is L. 1, 14s." The following are the valuations of several gentlemen of the value of carrots in the way of fattening cattle:

	per ton.
Mr Mellish of Blyth, a general valuation of horses, cows, and hogs,	L. 1 0 0
Mr Stovin of Doncaster, hogs bought lean, fattened, and sold off,	4 0 0
Mr Moody of Ratford, oxen fattened, and the account accurate,	1 0 0
Mr Taylor of Bifrons, saving of hay and corn in feeding horses,	1 0 0
Mr Le Grand of Ash, fattening wethers,	0 13 9
Sir John Hoby Mill of Bisham, fattening hogs,	1 6 0
Mr Billingsley, for fattening hogs,	1 13 6

Some other gentlemen whom our author consulted, could not make their carrots worth any thing: so that, on the whole, it appears a matter of the utmost doubt, so contradictory are the accounts, whether the culture of carrots be really attended with any profit or not. Thus Sir John Mill, by fattening hogs, makes L. 1, 6s. and Mr Stovin L. 4; but others could not fatten hogs upon them at all: and some of Mr Young's neighbours told him, that carrots were good for nothing except to *scour* hogs to death. The experiment of Mr Le Grand upon wethers appeared to be made with the greatest accuracy; yet two circumstances seem to militate against it. 1. The sheep were put lean to them; whereas it is a fact well known, that if they are not half fat when put to turnips, no profit will result; and it is possible that the case may be the same with carrots. 2. He gave them also as much fine hay as they would eat.

68
New experiments recommended.

In this uncertain state of the matter, the only thing that can be done is to make a number of experiments with as much accuracy as possible, in order to ascertain the real value *per ton*: and our author endeavours to show, that there is no danger of losing much by experiments of this kind. "I have shown (says he), that they are to be cultivated for L. 4 *per acre*, left on the ground for sheep. Suppose the crop only two bushels at 70 lb. each, *per rod*, 320 *per acre*, or ten tons; it will readily be agreed, that such a produce is very low to calculate upon, since 20 tons are common among carrot-cultivators. It appears from Mr Le Grand's experiments, that a wether worth L. 2, 5s. eats 16 lb. of carrots, and four pounds of hay *per day*: dropping the hay, and calculating for sheep of less than half that size (which are much more common), it will be perhaps an ample allowance to assign them 12 lb. of carrots a day. If they are, as they ought to be, half fat when

put up, they will be completely fattened in 100 days. At this rate, 20 wethers will, in 100 days, eat 11 tons, or very little more than one moderate acre. Now, let it be remembered, that it is a good acre of turnips which will fatten eight such wethers, the common Norfolk calculation: from which it appears, that one acre of carrots are, for this purpose, of more value than two of turnips.—Further, let us suppose horses fed with them instead of oats: to top, cart, and pack up, 10 tons of carrots, I know may be done for 20s.—an acre, therefore (other expences included) costs L. 5. Fifty pounds weight of carrots are an ample allowance for a horse a day: ten tons, at that rate, last three horses for five months. But this L. 5 laid out in oats at 16s. *per quarter*, will purchase little more than six quarters; which will last three horses, at two bushels each *per week*, no more than two months; a most enormous inferiority to the carrots."

In the same volume, p. 187. Mr Young gives an account of another experiment made by himself on the feeding of lambs with carrots. The quantities they eat varied excessively at different times; thirty-six of them consumed from five to ten bushels *per day*; but on an average, he rates them at four bushels of 56 pounds *per day*. In all they consumed 407 bushels from November to April, when they were sold and killed fat. At putting upon the carrots, the lambs were valued only at L. 18, but were sold in April at L. 25, 4s.; so that the value of the carrots was exactly L. 7, 4s. or about 4d. *per bushel*. This price he supposes to be sufficient to induce any one to attempt the culture of carrots, as thus he would have a clear profit of 40s. *per acre*; "which (says he) is greater than can attend the best wheat crops in this kingdom." The land on which the carrots grew was sown next year with barley, and produced the cleanest in the parish; which contradicts an assertion our author had heard, that carrots make land foul. The grass upon which the sheep were fed with the carrots, and which amounted to about an acre, was very little improved for the crop of hay in 1781, owing to the dryness of the season; but in 1782 was greatly superior to the rest of the field, and more improved in quantity: "for, instead of an indifferent vegetation, scattered thick with the centaurea scabiosa, filago, rhinanthus, crista galli, and linum catharticum, with other plants of little value, it encouraged a very beautiful sheet of the best plants that can appear in a meadow, *viz.* the lathyrus pratensis, achillea millefolium, trifolium repens, trifolium ochroleucum, trifolium alpestre, and the plantago lanceolata.

In the same volume of the Bath Papers, p. 227, Mr Billingsley gives an account of the comparative profit of carrots and cabbages. Of the former, however, he obtained only seven tons 15 cwt. *per acre*; the cabbages produced 36 tons: nevertheless, according to him, the profit of the former was L. 5, 8s.; of the latter, only L. 3, 11s. In a paper on the culture of carrots by Mr Kirby of Ipswich, vol. 3. p. 84. he informs us, that he never determined the weight of an acre, but reckons the produce from 200 to 500 bushels; which, at 56 lb. to the bushel, is from five to ten tons and an half. In the same volume, p. 320, the Rev. Mr Onley seems to prefer the culture of carrots to potatoes. "However valuable (says he), from ease of culture, and greatness of produce to the poor, especially in all small spots,

Carrots

Carrots compared with cabbages.

71
Culture of carrots preferred to potatoes.

⁷² ^{Carrots.} spots, I doubt, unless near great towns, whether, on a farming plan, potatoes be so eligible as other herbage or roots; especially as carrots, which I cannot but *surmise* (for my trials are too trivial to venture bolder language), deserve every encouragement, even on soils hitherto thought too heavy for them.—I am from experience convinced, that an acre of carrots will double in the quantum, of equally hearty provender, the product of an acre of oats; and from the nature of their vegetation, the nice mode of cultivation, and even of taking them up (all of which, expensive as they are, bear a very inferior proportion to the value of a medium crop), must leave the land, especially if taken off it in an early period, so mellow for the plough, as to form a seed-bed for barley equal to any fallow-tith.

Mr Onley's desideratum was a substitute for oats to feed horses; of which great numbers are kept in his county (Essex). Potatoes, he observes, are excellent for *small* pork, when baked or boiled, mixed with a little barley-meal; but for large hogs, they are most profitably given raw, if these have at the same time the shack of the barn door in threshing season, &c. In the 5th volume he resumes the subject, and acquaints us, that he applied a single acre in his bean-field to the culture of carrots, which generally produced 400 bushels; and this he considers as a small produce. "I am, however, sensible (says he) that they will amply repay every expence of the finest culture; and should, from their extensive utility on sound, deep, and friable land, be every where attempted. Some of my neighbours, who have been induced to try them on rather a larger scale, with finer culture, and fresher soil, have raised from 600 to 900 bushels *per* acre, and applied them more profitably, as well as more generally, than any other winter-herbage, to deer, sheep, bullocks, cows, and horses. At the lowest calculation, from our little trials, they are computed to exceed turnips in value one-third, as to quantity of food; but are far superior in what arises from convenience for the stable; where to us they seem to be a substitute for corn to all horses, at least such as are not used in any quick work; and partially so with corn for those that are."

⁷² Superior to turnips and oats.

In making a comparison betwixt the profit on oats and carrots, Mr Onley finds the latter exceed by no less than L. 2 : 15 : 8 *per* acre. His method of cultivation is to sow them in March or April; to hoe them three times, harrowing after each hoeing. Sometimes he leaves them in the ground till after Christmas, taking them up as wanted; but of late he takes them up in October, in dry days, putting them directly into small upright cocks of 10 bushels each, covered entirely with the tops cut off.—Thus they appear to dry better than in any other way, and bear the weather with very little loss. If, after being thus dried, they are carried into any barn or shed, it will be better, if they are in large quantities, not to pack them close, on account of the danger of heating, but rather to throw them promiscuously into heaps, with a little straw over them. When perfectly dry, they do not in general require any washing, except for horses regularly kept in the stable.

SECT. VII. Turnips.

THESE have long been in such general use as food for cattle, that the profit on raising them might be real-
N^o 159.

sonably thought to be altogether certain; nevertheless, Mr Young, in the paper already quoted, informs us, that "turnips dunged for are universally a losing crop; for if they are stated from 30s. to 40s. an acre, their value does not amount to the dung alone which is spread for potatoes; yet the latter pays that dung, all other expences, and leaves a profit sometimes considerable. I admit that turnips fed upon the land will prepare better for corn; but that is by no means the question. Would not the dung raised in the farm-yard by the consumption of the potatoes, supposing it spread on the potato acre, make that produce more than the turnip one? I have no doubt but it would give a superiority. But turnips are liable to great failures, and cannot be relied on late in the spring; potatoes may; and are applicable to uses to which the other root cannot be applied."—In the second volume of the Bath Papers, p. 101. we have a comparative account of the value of turnips, turnip-rooted cabbage, and lucerne, as food for cattle. The result of this writer's observations is, that "when sheep are allowed as many turnips as they can eat (which should always be the case when they are fattening), they will, on an average, eat near 20 pounds each in 24 hours.—An acre of turnips twice hoed, will, if the land be good, produce about 50 tons; which will, on the above calculation, maintain 100 sheep 52 days. The sheep mentioned weigh 20 pounds *per* quarter.—An acre of turnip-rooted cabbage will maintain 100 sheep for a month, and sometimes five weeks; but an acre of Scots cabbages will maintain 200 sheep a full month." The number fed by lucerne is not determined.

⁷³ Turnips. Their culture generally attended with no profit.

⁷⁴ Compared with other vegetables as food for cattle.

The greatest disadvantage which attends a crop of turnips, is their being so ready to be damaged by the fly, which sometimes destroys them so completely, that they must be sown over again two or three times the same season, and even this without any certainty of success. Innumerable methods of avoiding this evil have been projected, which may all be reduced to the following classes: 1. Steeping the seed in certain liquids. 2. Fumigation of the fields with the smoke of certain herbs. 3. Rolling. 4. Strewing foot, lime, ashes, &c. on the surface of the ground. It is very difficult, however, to determine, with any degree of certainty, whether remedies of this kind are effectual or not; because sometimes the turnips are not injured though no precaution has been made use of: and when this happens to be the case, after the use of any supposed preventative, the preservation of the crop is ascribed to the use of that preventative, whether it be really efficacious or not.—The virtues of sleeps seem to have been fully ascertained by Mr Winter Charlton near Bristol, of whose experiments an account is given in the Transactions of the Society for Encouraging Arts, vol. 5. The feeds were of the Dutch kind, sowed on beds in the kitchen-garden in drills about 12 inches distant, an inch and a half deep, on the 11th of May 1786. The beds had been prepared with rotten dung in May 1785, and afterwards sown with cabbages. The quality of the turnips is exhibited in the following table; the best being marked 1; and those of inferior quality, 2, 3, &c. The observations were taken on the 26th of June.

⁷⁵ The fly occasions the great inconvenience in turnip culture.

Another set of experiments was made with the green Norfolk turnip, drilled an inch and an half deep, the rows one foot distant, on beds eight feet three inches long, and two feet wide; half a drachm of seed allowed for each bed, steeped and mixed with various substances like the former. The seeds were drilled upon unmanured ground on the 20th of June 1786, and the observation made on the 17th of July. None of the beds were found free from the ravages of the fly; but the seeds which had been steeped in train-oil and linseed-oil were much more free from this injury than the others. The linseed-oil, as in the former experiment, was found inferior to the train-oil, which was supposed to have been owing to its being kept in a bottle that had formerly held oil of turpentine. The leaves of the steeped seeds were of a much darker green than the others, appeared twice as thick in bulk and luxuriance, and the plants were considerably larger than those of the other kinds. The substances mixed with the rest were soaper's ashes, wood-ashes, pounded gun-powder, brimstone, slacked lime, foot, barton-draining; sometimes mixed together in various proportions, and sometimes with the addition of a portion of sifted mould.

These experiments show, that no dependence can be had on steeps or mixtures of any kind with the turnip-feed; though the train-oil and linseed-oil seem greatly to have forwarded the vegetation of the plant. It does not appear that fumigation† has ever been tried; nor indeed does it seem easy to be tried in such a manner as might ensure success.—In the fourth volume of the Bath Papers, Mr Gullet of Devonshire gives such directions for performing the operation as he thinks would be productive of success.—In a preceding paper he had explained the good effects of fumigating orchards; but the case with these must be very considerably different from a field of turnips. The trees in an orchard are elevated above the ground, and the smoke naturally ascends, and is blown along their tops; but in fumigating a large field of turnips, it must creep along the ground in such a manner as is by no means agreeable to its na-

ture; and without an excessive degree of labour, as well as a vast quantity of burning materials, there cannot be the least hope of success. Mr Gullet's directions are as follow: "If the turnip-ground be spaded and burnt, or the weeds, &c. burnt without spading, the fumigation thereby may suffice to chase such of the winged tribe from thence as are then there; but in all cases, when the field is ploughed and ready for sowing, let heaps be made at different places and intervals round by the hedges and boundaries of the turnip-ground, and some few scattered through the field; then, as soon as the seed is sown, let the heaps on the windward side and the scattered ones be lighted and kept smothering during the continuance of the wind in that quarter; the less the fire, and the more the smoke, the better. Should the wind happen to shift, those heaps on the quarter it shifts to must then be lighted and kept smothering in like manner; so that, during the growth of the tender turnip leaf, and until it becomes rough and out of all danger, this fumigation and smoke, over and across the field, must be continued from one quarter to the other; which, I venture to assert, will effectually deter and prevent any winged insect-tribe from approaching the turnip-ground; nay more, if there already, it would most completely drive them from thence, as such delicately formed insects (which can only feed on the most tender leaf) would be ill able to continue long in such a smother of fire and smoke. The consequence is obvious and certain, that if the fly be kept from approaching the field, the turnip-crop is safe; and few, I believe, will disagree with me, that *prevention is better than remedy*."

Our author does not say that he has ever tried this method with turnips; but lays great stress upon his success in a similar experiment with cabbages, in order to preserve them from the caterpillar. To make the matter more sure, however, he recommends the trailing of a bush of elder over the turnip field at the time of harrowing or brushing in the seed: but this remedy has by numberless experiments been found insignificant, and by those above related seems even to be pernicious: so that whatever good effects we can expect from this method, must depend on the fumigation alone; and even this is attended with very great uncertainties, as has already been observed.

Rolling promises to be of service when the young turnips are attacked by snails, who frequently destroy them; but it cannot be supposed to have much effect in destroying flies, these being too numerous and too minute to be effectually crushed by the roller; and indeed, though this has been frequently recommended, we have no decisive proofs of its having ever been attended with any good effect.

The strewing of foot, lime, ashes, &c. upon the ground, have been determined ineffectual by the experiments already related, at least when applied before the turnips come up; and there seems to be little hope of their proving more effectual even when applied after the crop has appeared above-ground. We may argue indeed *a priori* about the taste or smell of foot, lime, &c. being disagreeable to insects; but of this we have no proof: and even though this were the case, the leaf soon emerges from under this covering, or the insects will feed on the under part of the leaves, where these substances cannot lie. It is evident, therefore, that very

77
Mr Gullet's directions for
fumigation.

Turnips.

little can be expected from any of the methods hitherto proposed either by way of cure or prevention. The more probable methods are,

79
Early sowing recommended.

1. To sow the turnips at such a season of the year that they may be well grown before the fly makes its appearance. In the Bath Papers, vol. iv. p. 132. Mr Wimpey observes, that, in order to procure food for their cattle in the spring before the grass is grown, farmers are obliged to postpone the sowing of turnips beyond the natural time of vegetation; but were turnips to be sown in April, as soon as the season would permit, it is very probable that there would be as great a crop of them as of other vegetables usually sown in these months. On account of the delay in sowing, however, for the reason already mentioned, the success of the farmer becomes exceedingly precarious, unless he is so fortunate as to have a few rainy days, or cloudy weather and frequent showers, soon after the seed is sown: and this our author supposes to be the true reason why the turnip is a more uncertain article than any other. But though speculations of this kind have a great show of probability, there is not any experiment hitherto published, even by our author himself, by which the truth of them can be absolutely ascertained. Our author, however, is of opinion, that none of the common methods proposed can answer any good purpose, farther than as by means of them the vegetation of the plant may be invigorated. Mr Wimpey recommends ashes, foot, or a rich compost of lime and dung, used in sufficient quantities; but the method of using them is, either to sow them with the seed, or rather by themselves immediately before, and to harrow them well in, that they may be completely incorporated with the soil. This for the most part would so invigorate and encourage the growth of the plants, as to be an overmatch for the most vigorous attacks of the fly.

80
Sowing a great quantity of seed.

2. Another method proposed for securing turnips from the fly, is by sowing such a quantity of seed as will be more than sufficient for the consumpt of the insects. This we find recommended in a letter to the Bath society by a gentleman-farmer in Essex, vol. ii. p. 238. His method is to make the land clean and fine as soon as the season will permit, and to sow four pints *per* acre. It may be objected, that if the fly does not take them, the plants will stand so thick, that they cannot easily be hoed; but this may be obviated by harrowing them first, which will make them fit for the hoe. There can be no expectation of a crop if the fly takes them when only a pint of seed is sown *per* acre; but this gentleman remarks, that he has not in any one instance missed of a crop when he sowed four pints; because, though the fly has sometimes destroyed more than one half, and much damaged the other, still there was a sufficient number left behind. He also agrees with other of the Society's correspondents, that the ground should be well dunged and manured previous to the sowing of turnips, as this makes them grow vigorously, so that they quickly get into the rough leaf, in which state the fly will not touch them.

81
Manuring in autumn preferable to spring manure.

In the same volume, a gentleman of Norfolk remarks, that manuring the ground in autumn for turnips is preferable to the doing so in spring. This discovery he made in consequence of the following accident.—“A neighbouring farmer, not having a sufficient quantity of manure for all his turnip land, was under the necessity

of sowing four acres unmanured. The effect was, that the turnips on the manured part of the land were mostly eaten off by the fly, while four acres unmanured escaped without injury.” In consequence of having observed this, the gentleman made a similar experiment, by manuring five acres well for turnips, and tilling three acres and an half in the usual way without any manure. The manured crops were almost all destroyed by the fly, so that he was obliged to sow most of the land over again. The three acres and an half which had no manure were entirely free from injury, though the plants were much smaller than those of the manured ground which came up. Not content with this trial, however, he repeated the experiment, by manuring six acres of wheat stubble in autumn, ploughing it in immediately, and leaving it to incorporate with the earth during the winter: the turnips which grew upon this were as large as if the ground had been manured in the spring. This experiment was repeated with surprising success in two succeeding years; whence he infers, that the fly is either engendered in the new dung or enticed by it. But when the manure is laid on in autumn it loses its noxious qualities, though it still retains its nutritive ones.—This conclusion, however, does not appear to be well founded; for it is certain from undoubted experience, that turnips which have been well manured in the common way, have sometimes escaped any injury; while others, which have got no manure at all, have been almost totally destroyed. Another material advantage, however, which this correspondent observes is to be derived from manuring in autumn is, that all the seeds contained in the manure, and which are of course carried on the land with it, vegetate almost immediately, and are mostly killed by the cold of the succeeding winter, while the few that remain can scarce escape destruction from the ploughshare.

Mr Wimpey is also of opinion, that it is proper to sow a large quantity of seed; but thinks two pounds will be sufficient for an acre. A few ounces indeed would be sufficient to stock the land; but as the article is so precarious, he thinks it by far the safest way to allow seed in plenty, and reduce the plants afterwards by harrowing. He observes also, that it is of great consequence to have seed both good in quality and of the best species. He prefers the large and green topped, as being the most sweet and juicy; others give the preference to the red or purple-topped, as being hardier: but at any rate, the seed from the largest and finest transplanted turnips, of whatever sort, is greatly to be preferred, even though it should cost double or treble the price. Such as is sold by the seedsmen in London he found generally of a mixed kind, and often in great part not worth cultivating. “Whether plants from new or old seed are most secure from the depredations of the fly (says he), is perhaps a question which cannot be easily determined even by experiments; for concomitant circumstances are frequently so much more operative and powerful, as to render the difference between them, if there be any, imperceptible. It is, however, known to every practical man, that new seed sprouts or vegetates several days before old; and I think more vigorously: and it is equally well known, that the healthy and vigorous plants escape the fly, when the stunted and sickly seldom or never escape them. It

82
Mr Wimpey's opinion of sowing a great quantity of seed.

Of the quality of the seed.

Turnips.

Turnips. It should seem then, that new seed, *ceteris paribus*, is more secure from the fly than old; and for my own use I would always prefer it."

84
Of sowing
turnips
with other
grain.

3. The sowing of turnips along with other grain. — This, of all others, seems to be the most eligible and efficacious. In the second volume of Bath Papers, p. 210. an Hertfordshire correspondent gives an account of the success of an experiment of drilling turnips with wheat. A small field of spring-wheat was drilled in rows two feet apart; and in the month of May turnips were sown by hand in the intervals. They came up very well, and were thinned once by the hoe. The crop of wheat turned out better than another field of the same soil sown broadcast in autumn, though it ripened somewhat later. The turnips were no other way injured by cutting it, than having some of the large leaves trodden down by the reapers. After harvest the weeds were cut up round the turnips with a hand-hoe, and they grew very large and vigorous. They were of the purple and white long kind, and the crop proved nearly as good as the same land produced in common. An excellent crop of barley and clover was got from the same field afterwards.

85
With
wheat.

86
Mr Ander-
don's expe-
riments of
sowing
them with
beans.

In the third volume of the same work we find an account of several successful experiments in sowing turnips between rows of beans. The advantages of this method are strongly set forth by R. P. Anderdon, Esq; who made some of the experiments, and are as follow: "1. You may have a crop of beans and turnips on the same field the same year. 2. The bean-crop being well horse-hoed, no ploughing is wanted for turnips, for which the best Norfolk farmers give five ploughings. 3. It is hoed cheaper, more effectually, and consequently more profitably, than in any other way. 4. The ground is kept clean from weeds. 5. It is in order for a Lent crop the succeeding year with one earth. 6. The ground is kept in heart, if not improved, by fallowing your alleys. 7. It brings the plant to perfection in poor ground, where it would not become so otherwise. 8. It doubles the crop in any ground which Mr Anderdon has had experience of. 9. You have the crops more within your own power in this than in any other method, let the seasons turn out as they will. 10. You may have on the same ground a bean and turnip crop annually, if the land be suitable, and you think proper. 11. The clay farmer, by this mode, renders land which is naturally unfit for turnips, so free and open by seasonable horse-hoings, that it will bring this useful plant to great perfection."

87
Objections
by the Bath
Society.

On this paper the society made some remarks, and stated the following objections: 1. The same soil cannot be proper for both crops. Scotch cabbages are more adapted for a bean soil; and they wished him to repeat the experiment with cabbages instead of turnips betwixt his beans. 2. The Norfolk farmers rarely use more than three ploughings for turnips, instead of five, as Mr Anderdon represents, unless the ground be full of couch-grass. 3. They think him too sanguine in his expectations of having double crops on the same field. 4. Nothing renders a clay soil so free and open

as to have it exposed to frosts and snow by being laid up in high ridges in January and February; but, on Mr Anderdon's plan, this cannot be done, unless the turnips are lessened in value by being fed off in autumn.

Turnips.

These strictures were sent to Mr Anderdon before the papers were printed, but did not make any alteration in his opinion; and he replied to the following purpose:

88

1. *The same soil cannot be proper for beans and turnips, &c.*—Granted.—But had Mr Anderdon adhered rigorously to this rule, he would have sowed no turnips at all, not having on his farm any soil altogether proper for that crop; "but (says he) while I can get in single rows, four feet asunder or more, from half a dozen to half a score tons of turnips per acre, after, or rather between, a crop of beans in my heavy lands, I shall feel that product here more beneficial than to drop the mode. I believe the medium of the two, so far as I can judge by the eye or get information, to be superior to the average produce of prepared fallow turnip crops in 10 miles round me."—On this the Society make the following remark: "The question here is, Whether, if instead of turnips, Mr Anderdon had planted his beans two feet distant only, the extra produce of his crop would not have exceeded in value that of his turnips? We think they would, as these intervals would freely admit his horse-hoe between the beans."

Mr Anderdon then proceeds to acquaint the committee, that he had tried the experiment as they wished with Scotch cabbages instead of turnips betwixt the rows of beans; but the crop of the turnips was so much preferable, that he found himself inclined to suppose the cabbage would not get to so great perfection there as to be profitably introduced on a large scale, for want of the great quantity of dung necessary for that crop, and which could not be procured in that part of the country. He further remarks in favour of turnips, that they have an abundance of very small lateral fibrous roots, which run so far in search of food, and feed as ravenously where they can penetrate, as those of almost any other vegetable; and the plant certainly derives more nourishment from those than from its tap-root (A). Those fine fibrous roots, almost imperceptible to the eye, issue chiefly from the apple or body of the turnip, and get into the richest part of the soil near the surface, and will bring the plants to a considerable magnitude in heavy lands adapted to beans, when mellowed by the horse-hoe. Some of his turnips weighed ten pounds each: and if he could have only two such turnips on every square yard, it would be at the rate of 43 tons per acre.

2. *The Committee doubt of the possibility of doubling the crop.* Mr Anderdon gives the following explanation. "I have made many comparative trials on turnips between this mode and broad-cast sowing, and always found on my ground the horse-hoed crops the best. But here, in denoting the benefits of the horse-hoe by its doubling a crop, I wish to be understood, that if, in soils like mine, a crop be drilled, leaving proper in-

5 B 2

tervals

(A) Here the Society remark, that this is not the case with those kinds of turnips which grow chiefly above ground, and which are generally the best crops, and most capable of resisting the frosts.

Turnips.

tervals for horse-hoeing, and one part be horse-hoed the other not, the horse-hoed part will double the other in product."

Mr Anderdon, in the course of his reply to the committee, gives an account of another experiment he made in consequence of being deficient in winter fodder for his cattle. By this necessity he was induced to sow turnips wherever he could; and on the 18th of July drilled a single row between his drilled wheat. On the 20th and 22d of August he drilled four rows of winter vetches in each interval between the turnips, at the rate of less than one peck and three quarters of seed to an acre. "The turnip crop (says he) is very acceptable, and my vetches succeed beyond my warmest expectation; are thick enough, and give me the pleasing prospect and hope, that I shall not, when my dry meat is gone, want a seasonable supply of early green fodder that will last me till my lucerne comes on."

89
Mr Pavier's opinion.

This subject is further considered in the same volume by Mr Pavier, who viewed Mr Anderdon's turnips, and gave in a report of them to the committee. He supposes a crop of beans drilled in single rows at four feet distance, and the turnips drilled in the intervals, according to Mr Anderdon's method, there will then be four rows of 17 feet in length to make a square perch; whereas Mr Anderdon's rows were only 15 feet 8 inches in length; and this disparity in length will make a difference of weight on a perch from 230 to 249 pounds, and on an acre from 16 tons 8 cwt. 2 qrs. 8 lb. Mr Anderdon's produce, to 17 tons 15 cwt. 2 qrs. 24 lb.—Each turnip at this distance (*viz.* four feet from row to row, and nine inches in the rows) must occupy a space of three square feet; consequently the greatest number produced on an acre must be 14,520; but if sown in broadcast, twice hoed, and the distance on an average 15 inches, each turnip will then occupy little more than one foot and an half, and the number produced on an acre may be about 27,920; an excess which may reasonably be supposed to overbalance the value of the beans, let us suppose the crop as great as we can reasonably do. Thus far the argument seems to lie against this method of cultivating beans and turnips together: but on the other hand, Mr Pavier considers it probable that the expence of drilling and horse-hoeing the beans, together with drilling the turnips in the manner Mr Anderdon did, must be considerably less than that of fallowing and preparing the ground, and sowing the turnips in broadcast; to which we must likewise add the facility of hoeing the drills in comparison of the broadcast. But besides these, the great advantage arising from this method, and which, if certain, gives it a decided superiority, is, "the great chance, if not an almost certainty, of preserving the turnips from the depredations of the fly." Mr Pavier was inclined to think that this must be the case, as Mr Anderdon had such crops repeatedly without any damage of that kind: but the committee differ from him, and think that this must have proceeded from some other cause; though they do not assign any reason for this opinion. "The principal point (says Mr Pavier), in determining this question, seems to me to be this: if the crop of beans drilled as above, after deducting the seed, and some additional expence in taking the crop off the ground without injuring the turnips, can be, one year

with another, supposed to be as valuable as the quantity of turnips that might be reasonably expected in the broadcast method more than in the other, I should not hesitate to declare in favour of drilling between the beans."

Thus far the argument seems to be carried on *a priori*. Mr Wimpey, in the letter already quoted, inclines to the practice of sowing turnips between beans planted in rows. "It exactly corresponds (says he) with all my observations on the successful vegetation of that root. A considerable degree of moisture is necessary to the rapid vegetation of that very juicy root, and nothing retains moisture equal to shade; and shade can be obtained and secured by no means so effectually on a large scale as in the intervals of tall growing plants, as beans or wheat planted in drills." The success of Mr Bult of Kingston near Taunton, leaves little room to doubt of the propriety of the method, and its success in preventing the fly. The beans were planted in drills not quite two feet asunder, on two plowings, horse-hoed three times, and the turnips sown in the intervals at the last hoeing. The field measured six acres and a quarter, and was a very good clayey soil, but had not been manured, nor had any dressing laid upon it for six years before. It produced this year three quarters of beans per acre, and 37 tons 5 cwt. of turnips. This field was also viewed by Mr Pavier, who makes the following observations upon it. 1. The turnips were sown promiscuously among the beans at the last hoeing, which was given about midsummer; from which time nothing was done but drawing off the beans and carrying them off the land. 2. The crop of beans was believed to be considerably above 20 bushels per acre, which is much more than were produced by any other method that season in the neighbouring part of the country: and as Mr Pavier had this account before he saw the turnip crop, he did not expect any thing considerable from the latter; but as it turned out, the produce must be accounted highly profitable, when we consider that there was no crop lost, no preparation, dressing, nor any expence whatever, excepting the price of the seed and sowing it. 4. This he considers as one of the strongest recommendations of the drill husbandry he ever knew or heard of; but he is of opinion that it never can answer except where the ground is perfectly clean and free from weeds, by the crops having been horse-hoed for a few years before. 5. He thinks the beans ought to have been planted at wider intervals, by which the sun and air would be freely admitted, and the plants would also be less damaged by the operation of the hoe.

Mr Pavier likewise informs the Society of two other experiments on a similar plan; but with this difference, that the turnips were sown among the beans at the second horse-hoeing. The turnip crops were very good, and the beans more than double the value of those raised in the usual mode of husbandry. "I think it is very evident (says he), that the beans preserve the turnips from the fly; and as no expence or trouble attends the practice, I apprehend it will soon become more general." The Society own, that the uncommon success of Mr Bult's experiment seems to militate at least against what they said on Mr Anderdon's letter; but they insist that the cases are by no means similar. "Though the land (say they), in both instances, is called a heavy clay,

Turnips.

90
Other experiments on sowing turnips among beans.

Turnips.

clay, they are very different. Mr Anderdon's is poor, wet, and cold; the other a good rich clay; and we apprehend naturally mixed with a kind of marle, which is called clay by persons not thoroughly acquainted with the nice distinction of soils apparently alike, but very different in their nature. Our principle therefore, that cold wet clay lands are unsuitable for turnips, remains unaffected by this experiment; and general practice confirms the truth of the theory."

In another letter, Mr Pavier gives a more particular account of the two other crops of beans and turnips raised upon Mr Bult's plan. The beans were drilled in rows about 22 inches distance, twice horse-hoed, and the produce from about 25 to 30 bushels the computed acre, or from 30 to 36 bushels the statute acre. The preceding summer had been very unfavourable to beans, and the produce per acre in the common husbandry did not, on an average, equal a third part of this quantity. One of these crops was superior to that of Mr Bult: they were sown upon a field of nine computed acres on the 10th of June, after the second horse-hoeing; but whether the second hoeing was performed too soon, the ground not clean, or whatever might be the cause, the beans were weeded twice by hand afterwards; and he is of opinion, that the turnips were somewhat benefited by it. Mr Pavier was assured by a very intelligent farmer, that this was the best crop of turnips he had ever seen. The turnip-feed in the other crop was put in between the rows of beans by a hand-drill; but the work was badly performed, the plants coming up in some places vastly too thick, and in others as much too thin; but wherever they happened to be of a proper thickness, the farmer told him it was one of the most profitable crops he ever had. The soil was wet, heavy, and not very favourable for turnips. Hence Mr Pavier deduces the following conclusions. 1. That with respect to beans in particular, the drilling and horse-hoeing is vastly superior to the common mode of husbandry. 2. That the beans are undoubtedly a good preservative of the turnips from the depredations of the fly. 3. That as by this method no crop is lost, and consequently no rent, but a mere trifle of expence (if any) chargeable to the turnip crop, it must be one of the most profitable as well as the most certain method of propagating that useful root ever yet practised.—He still insists, however, that if he had an opportunity of trying this method, he would drill the beans in rows at a greater distance, that the turnips might be hand-hoed easily; and that he should prefer the London tick-bean to any other, by reason of their shortness and being such bearers; that he should also take off their tops as soon as the under blossoms began to decay; which, he supposes, would be of great service.

91
Instrument
for trans-
planting
turnips.

Bath Pa-
pers, vol. iv.
p. 126.

We shall close this dissertation on the uses and culture of turnips with an account of an instrument used in Norfolk for transplanting them, and thus filling up the gaps which frequently happen in fields from the failure of the plants in particular spots. It is represented on the margin; and the construction and mode of using is obvious from the figure.—When the turnips are to be transplanted, the workman holds the long handle with the left hand, and the short one with the right hand drawn up. Put the instrument then

over the plant that is to be taken up, and with your foot force it into the ground; then give it a twist round, and by drawing it gently up, the earth will adhere to the roots of the plant in a solid body; then with another instrument of the same size take the earth out where the plant is to be put, and bringing the instrument with the plant in it, put it into the hole which has been made by the other; then keep your right hand steady, and draw up your left, and the earth and plant will be left in the hole with the roots undisturbed. In this operation two men must be employed, each of them having an instrument of the form represented on the margin. One man takes up a plant while the other fills his instrument with earth only, thereby making room for the deposition of the plant; so that the hole which is made by taking up the plant is filled with the earth taken out where the plant is to be put; which being deposited, he takes up a plant, and returns to the place he first set out from, the former man at the same time returning with the earth only; so that each man is alternately the planter, and each being employed both ways, the work goes on briskly.—This instrument was the invention of Mr Cubitt Gray of Southrepps, Norfolk.

Turnips being the grand basis of the Norfolk husbandry, Mr Marshall gives a very particular account of their culture in that county.—The species cultivated are, 1. The common *white stock*, called in many places the Norfolk turnip. 2. The *purple stock* is similar to the former, but its rind is of a dark red or purple colour; its size in general smaller, and its texture closer and firmer than that of the common white-stock; it also stands the winter better, and is more succulent in the spring, but it is not so well relished by cattle as the former; whence it is less generally cultivated. 3. The *pudding stock*, the *tankard-turnip* of the Midland counties, is in shape so perfectly different from the common sort, that it might be ranked as a distinct species. It rises in a cylindrical form, eight, ten, or twelve inches high, standing in a manner wholly above ground; generally taking a rough irregular outline, and a somewhat reclining posture. It very much resembles the common turnip, and is by much its most formidable rival. In many respects it seems to be superior, particularly in being readily drawn, and eaten off by sheep with much less waste than the common turnip.—The disadvantage is, that they are liable to the attacks of frost, by reason of their standing so high above the surface of the ground; so that on the whole, Mr Marshall concludes, that the common white turnip is to be preferred to every other.

In Norfolk, turnips are sown upon every species of arable land. Marl is found to be highly beneficial; and by means of this manure, a soil naturally unfit for turnips may be rendered proper for it. They succeed barley rather than any other crop; some few are sown on wheat or pea stubble after harvest; but this is not a general practice. The manures in greatest reputation for turnips are dung, with a greater or smaller admixture of mould; *malt-coombs* are also in good repute, and oil-cake is used by a few individuals; "but it may be said, that nine acres of ten of the turnips grown in east Norfolk are manured with muck."—The quantity of dung set on for a crop of turnips generally depends on the quantity on hand,

Cultivation
of turnips
for early
consump-
tion.

95
Method of
sowing,
and culture.

When the turnips are intended for early consumption, the sooner they can be got into the ground the better; but when they are intended to stand the winter, the beginning of July is thought soon enough. The most general rule is to begin sowing about a week before mid-summer, and continue till about a fortnight after, viz. from the 17th or 18th of June to the 7th or 8th of July.—Broad-cast sowing is universal, in the quantity of two pints to an acre. The seed is covered by two lines of a pair of light harrows drawn backward, in order to prevent the lines, which usually point something forward, from tearing up the clods, and burying the seed too deep. The horses are universally *walked* one way, and *trotted* back again in the same place. This is an excellent custom; the quick zig-zag motion of the harrows at once assisting to level the surface, and to distribute the seeds more evenly.—They are universally hoed; and unless they be sown very late, are generally hoed twice. The distance of time between the sowing and the first hoeing depends upon the soil and season; the size of the plants being the only guide. When turnips are suffered to grow too large before they are hoed, the plants are difficult to be set out singly, and are liable to be drawn up by weeds, thereby acquiring a slender upright tendency; whereas their natural growth, in their infant state, is procumbent, spreading their first leaves on the ground, and taking the form of a rose.—If the hoe be put in too soon, the plants which are set out are liable to be buried, and their tender roots disturbed in the act of setting out the neighbouring plants. The time for hoeing, as directed by the most judicious husbandmen, is when the plants, as they lie spread upon the ground, are about the size of the palm of the hand: if, however, seed-weeds be numerous and luxuriant, they ought to be checked before the turnips arrive at that size, lest by being drawn up tall and slender they should acquire a weak and sickly habit. The proper distance depends upon the nature of the soil and the time of sowing; such as are sown early, in a rich productive soil, require to be set out wider than those sown late on a soil of a contrary nature. If the soil be at par, the distance ought to be regulated by the time of sowing: if this be at par, the nature or state of the soil should be the regulator.—Mr Marshall complains of the conduct of the Norfolk farmers in general in this respect, who “hack out their turnips 14, 15, or perhaps 18 inches asunder, without any regard to the state of the soil, or time of sowing. This practice was established while the Norfolk soil was full of marl, and new to turnips; and when, it is probable, 11 or 12 inches in diameter was no uncommon size, with tops proportionally large and spreading; and 14 or 15 inches might then be a proper distance. But now, when the efficacy of marl is lessened, and the soil no longer the favourite of turnips, which seldom reach more than seven or eight inches in diameter, it is ruinous and absurd to continue the practice.”

Turnips are cultivated either for seed, for sale, or for consumption. When cultivated for seed, it is sup-

posed in most parts of the kingdom that it ought always to be taken from transplanted roots; but in Norfolk they are frequently raised from such as are untransplanted. “It is a fact (says Mr Marshall) well understood by every husbandman here, that if the seed be gathered repeatedly from untransplanted roots, the plants from this seed will become coarse-necked and foul-rooted; and the flesh of the root itself will become rigid and impalatable. On the contrary, if it be gathered year after year from transplanted roots, the necks will become too fine, and the fibres too few; the entire plant acquiring a weak delicate habit, and the produce, though sweet, will be small. For the neck, or onset of the leaves, being reduced to the size of the finger (for instance), the number and size of the leaves will be reduced in proportion; and in a similar proportion will the number and size of the fibrils be reduced. From a parity of reasoning, it may perhaps be inferred, that when the neck acquires a thickness equal to that of the wrist, the size of the root will be in proportion.”

“With respect to the fibres or rootlings, this is a just inference; but with respect to the bulb, it is in a great measure erroneous. For a few generations the size of the bulb will keep pace with the increase of leaves and fibres; but after having once reached the limits which nature has set to its magnitude, it begins to revert to its original state of wildness, from which to its present state it has undoubtedly been raised by transplantation. The farmer has therefore two extremes to avoid. The one is discoverable by the thickness and coarseness of the neck, the scaly roughness of the bulb, the thickness of the rind in general, the foulness of its bottom, and the forkedness of its main or tap-root: the other, by the slenderness of the neck, the fineness of the leaf, and the delicacy of the root. The former are unpalatable to cattle, and are therefore creative of waste: the latter are unproductive, are difficult to be drawn, and do not throw out such ample tops in the spring, as do those which are, by constitution or habit, in a middle state between these two extremes. There is not, however, any general rule respecting how many years turnips ought to be transplanted successively, and how often they ought to be suffered to run up from the seed-bed: the soil and situation have, and other circumstances may have, influence on the habit and constitution of vegetables as of animals; and the farmer must attend alone to the state of the turnips themselves. Whenever he judges, that, by repeated transplantation, they have passed the acme of perfection, then it is his duty and interest to let them run up to seed without transplantation. In Norfolk it has been found, by long experience, that transplanting two, three, or four years, and letting the plants run up the third, fourth, or fifth, will keep the stock in the desired state. The time of transplanting is from Old Christmas to Old Candlemas. In the choice of plants, the farmer is not guided by size, but picks the cleanest plants without regard to size; or, more accurately speaking, he makes choice of such as are near, but not at or above, the state of perfection. In almost every turnip-field there are plants in various states: much judgment, therefore, is requisite in the choice of plants. A piece of good ground near a habitation is generally chosen for this purpose; but the method of planting is various: the plants

97
Method of
planting.

Turnips. plants are generally set in rows, at uncertain distances from one another." These distances our author has observed to be 16 or 18 inches, and the distance of the plants in them nine or ten inches; but the practice of a man who, he tells us, is indisputably near the head of his profession, is to plant them in rows two feet asunder, the plants in the rows being contiguous. The only culture acquired, is to keep the intervals clean-hoed; but when the seed begins to ripen, much care is requisite to keep it from birds. If the plot be large, it is necessary to employ a boy to scare them; but if it be small, and near the house, Mr Marshall has known the following expedient used with success. "On a slender post, rising in the midst of the patch of seed, was fixed a bell; from which a line passed into the kitchen; in the most frequented part of this hung the pull. Whoever passed the pull, rung the bell; so that, in a farm-house-kitchen, where a mistress and two or three maids were some of them almost always on the foot, an incessant peal was kept up; and the birds, having no respite from alarms, forsook their prey."

98
Method of
scaring
away birds.

99
Of drawing
the turnips

100
Snow
sledge de-
scribed.

The time of drawing commences about Michaelmas, and continues until the plants be in blow. The process of drawing, he says, "in severe weather, is an employment which nothing but custom could reconcile to those whose lot it is to go through it, namely, stout lads and youths; whose hands are frequently swelled until the joints are discernible only by the dimples they form;" nevertheless he never heard of any instance of bad effects from this circumstance. When the tops will bear it, their method of pulling is very expeditious: they pull with both hands at once; and having filled each hand, they bring the two together with a smart blow to disengage the soil from the roots, and with the same motion throw them into the cart. If the tops be cut off by the frost, or if this be in the ground, the turnips are raised with two tined forks named *crooms*. If the roots are buried under deep snow, it is removed by means of an implement called the *snow-sledge*. This consists of three deal-boards from one to two inches thick, 10 or 12 inches deep, and from seven to nine feet long, set upon their edges in the form of an equilateral triangle, and strongly united with nails or straps of iron at the angles; at one of which is fastened, by means of a double strap, a hook or an eye, to fasten the horses to. This being drawn over a piece of turnips covered with snow, forces up the latter into a ridge on each side, while between the ridges a stripe of turnips is left bare, without having received any material injury from the operation. Though it is customary, in drawing, to clear the ground entirely, our author met with one instance in which the small ones were left by a very good husbandman on the ground, both to increase in size, and to throw out tops in the spring; it being observable, that a small turnip sends up a top nearly equal to one whose bulb is larger. There is one inconvenience, however, arising from this practice, the plough is prevented from entering upon the soil until late in the spring; which, upon some soils, is an unsurmountable objection; tho' it may be very proper upon land which will bring good barley with one ploughing after turnips.

101
Method of
preserving
turnips.

Mr Marshall relates the following simple method, by which a Norfolk farmer preserved turnips through a considerable part of the winter season. Having cut

off their tops with a spade, he gave them to his cows, and carried the bulbs to a new-made ditch, into which he threw them, and then covered them up with straw, laying over it a quantity of bramble kids. Here they lay until wanted in a frost. They were then again carted by means of a fork, and given to the cattle, who eat them as well, or rather better than fresh drawn turnips; and in general they came out as fresh as they went in. Our author is of opinion, that this method might be extended to the preservation of turnips till the spring.

Turnip-
rooted
Cabbage.

SECT. VIII. Turnip-rooted Cabbage.

This plant may deservedly be reckoned next in value to the turnip itself. Its advantages, according to Sir Thomas Beevor, are, that it affords food for cattle late in the spring, and resists mildew and frost, which sometimes destroy the common turnip; whence he is of opinion that every farmer who cultivates the common turnip should always have part of his farm laid out in the cultivation of this root. For his mode of culture, &c. See AGRICULTURE, n° 170; and under n° 173 of the same article is given an account of Mr Robins's method of raising them. In another letter from Sir Thomas Beevor, Bath Papers, vol. iii. p. 489. he expresses his hope that the turnip-rooted cabbages he had would last until he should have plenty of grass for all his stock. To make a comparative estimation of the quantity of food yielded by the turnip-rooted cabbage and the common turnip, he selected some of each kind, and having girted them with as much accuracy as possible, he found, that a turnip-rooted cabbage of 18 inches circumference weighed $5\frac{1}{2}$ lb. and a common turnip of the same size only $3\frac{1}{2}$ lb; on trying others, the general result was found to be in that proportion. Had they been weighed with the tops, the superiority of the turnip-rooted cabbage would have been greater, the tops of them being remarkably bushy. They were weighed in the month of March; but had this been done at Christmas, our author is of opinion that the difference would not have been so great; tho' he reckons this very circumstance of their continuing so long to afford a nourishing food, an instance of their excellency above almost every other vegetable whatever.

102
Advantages
attending
the cultiva-
tion of this
root.

103
Compari-
son of the
quantity of
feed in this
and in the
common
turnip.

In the fourth volume of the same work, Sir Thomas gives an account of another experiment on five acres of turnip-rooted cabbage, four of which were eaten upon the field, the other was pulled up and carried to the stables and ox-houses. They were sown and cultivated as other turnips; the beasts were put to them on the 12th of April, and continued feeding upon them till the 11th of May. The cattle fed for this space of time were, 12 Scotch bullocks weighing 40 stone each; eight homebreds, two years old; fifteen cows full-sized; 40 sheep; 18 horses; besides 40 store hogs and pigs, which lived upon the broken pieces and offal without any other allowance for the whole four weeks. The whole value of the plant; exclusive of the feeding of the pigs, amounted, according to our author's calculation, to L. 18; and he says that the farmers would willingly give this sum in the spring for feeding as many cattle; "because it enables them to save the young shooting grass (which is so frequently injured)

104
Other ex-
periments.

Turnip-rooted Cabbage.

104
Disadvantages attending the cultivation of this plant.

105
Why every farmer ought to cultivate this plant.

injured by the tread of the cattle in the frosty nights) until it gets to such a length and thickness as to be afterwards but little affected by the summer's drought. Besides this, the tops or leaves are in the spring much more abundant, and much better food than those of the common turnip, as already observed; and they continue in full perfection after all the common turnips are rotten or worthless.

The disadvantages attending the cultivation of turnip rooted cabbages are, that they require a great deal of time and pains to take them up out of the ground, if they are to be carried off the field; and if fed where they grow, it requires almost an equal labour to take up the pieces left by the cattle. A great deal of earth is also taken up along with the root; and the substance of the latter is so firm and solid, that they must be cut in two in order to enable the cattle to eat them. To obviate some of these objections, it will be proper to sow the plants on rich and very light land; and as they are longer in coming to the hoe than the common turnip, it will be proper to sow them about the beginning of June.

In another experiment upon this plant by the same gentleman, the cabbages held out during the long and severe frost of 1788 without the least injury, though it destroyed three-fourths of all the common turnips in the neighbourhood. On the 21st of April 1789, the average produce of an acre was found to be somewhat more than $24\frac{1}{2}$ tons, though the tops had not sprouted above three inches. Considering the precariousness of turnips and other crops, Sir Thomas is decisively of opinion, that all farmers ought to have as many turnip-rooted cabbages as would afford and ensure them a full provision for their cattle for about three or four weeks during the latter part of the spring. This quantity he reckons sufficient, as the consumption, particularly when drawn and carried off the land, is attended with more trouble and expence than that of common turnips, especially if the soil be wet and heavy. In another letter, dated May 3. 1790, Sir Thomas Beever once more sets forth the advantages of having a crop of these vegetables during the spring-season. "In consequence (says he) of the very cold weather we have had here, the grass is but just springing: as the turnips are wholly eaten up, it occasions much distress among the farmers for want of some green vegetable food for their sheep and cattle; whereas, by the assistance of my turnip-rooted cabbages, I have abundance of the best and most nutritive food that can be found them." He then proceeds to recommend their culture "for the support of almost all live stock for the three last weeks of April, or first week of May, when the grass shoots late."

In the 4th volume of the Transactions of the Society for encouraging Arts, Mr Robins, who received a premium for raising the greatest quantity of this plant, informs us, that the soil on which it grew was a *stone braisb*, inclining to sand, not worth more than 10s. per acre; the preparation the same as for turnips. The manure was a compost of earth and dung, which he finds to answer better than dung. The seed was sown about the beginning of April on a clean spot of ground; and he commonly uses an old pasture where the sheep-fold has been in the winter, after taking away the dung, and digging it very shallow; "as the roots

N^o 159.

of the young plants (says he) might soon reach the dung or salts, which must consequently be left, in order to force them out of the fly's way." These insects, our author observes, are extremely fond of the turnip-rooted cabbage; much more so, he believes, than of common turnips. About the middle of June they should be planted out upon one-bout ridges raised by a double plough made for the purpose. Seven thousand plants are sufficient for one acre; but if only six are used, the roots will be the larger.

To determine how many sheep might be kept upon an acre of turnip-rooted cabbage, our author shut up 200 ewes with their lambs upon a piece of poor pasture-land of no great extent; the whole not exceeding ten acres. One ton was found sufficient for keeping them in sufficient health for a day. On giving them a larger piece of ground to run over, though it had been eat all winter and late in the spring; yet with this trifling assistance 13 tons of turnip-cabbage were made to serve 18 days; at the end of which the ewes and lambs were found very much improved, which could not have been expected from four acres of turnips in the month of April, the time that these were fed.

From some trials made on the turnip-rooted cabbage at Cullen House in the north of Scotland, it appears that the plant is adapted to the climate of every part of our island. The first trial was made in the year 1784. The seeds were sown about the middle of March in garden-ground properly prepared. The cabbages were transplanted about the middle of March that year into a dry light soil, well cleaned and dunged with rotten cow-dung, in rows three feet distant from each other, and at the distance of 20 inches in the rows. They were kept very clean, and the earth was hoed up to the roots of the plants; by which means they were probably prevented from attaining the hardness they would have otherwise arrived at; though, after all, it was necessary to cut the roots in two before the sheep could eat them. When thus cut, the animals eat them greedily, and even preferred them to every other food. The roots continued good for at least a month after the common turnips were unfit for use: some of them weighed from eight to ten pounds, and a few of them more. Other trials have since been made; and it now appears that the plant will thrive very well with the ordinary culture of turnips in the open fields, and in the usual manner of sowing broad-cast. From a comparative trial made by the earl of Fife upon this root with some others, the quantities produced upon 100 square yards of ground were as follows:

	Stone.	lb.
Common turnips	-	92 4
Turnip-rooted cabbage	-	88 0
Carrots	-	95 0
Root of scarcity	-	77 0

The turnip-rooted cabbage was planted in lines 20 inches asunder; the common turnips sown broad-cast, and hand-weeded, so that they came up very thick, being not more than three or four inches asunder when full grown. Two cows were fed for six weeks with the turnips, two with the turnip-rooted cabbage, and two with the root of scarcity for an equal time: the two fed with turnips gave most milk, and those with the root of scarcity the least. His lordship observes,

Turnip-rooted Cabbage.

Experiments at Cullen-house.

Swedish
Turnip.

serves, however, that carrots thrive better on his farm than any other crop: that his horses had been fed on them at the rate of two pecks a day, with no corn, and little more than half the usual quantity of hay. "They were kept at work every day from seven to eight hours, and were never in better order."

SECT. IX. *Swedish Turnip.*

108
Of the Ru-
ta Baga.

† *The Bee*,
vol. iii. p.
291.

THE ruta бага, or Swedish turnip, is a plant from which great expectations have been formed. It is said to be hardier than the common turnip, and of greater sweetness and solidity. It also preserves its freshness and succulence till a very late period of its growth, even after it has produced seed; on account of which property it has been recommended to the notice of farmers as an excellent kind of succulent food for domestic animals in the spring of the year, when common turnips and most other winter crops have failed, and before grass got up to furnish an abundant bite for feeding beasts. This peculiarity, so valuable, yet so singular as to have led many at first to doubt the fact, seems to be sufficiently ascertained by experiment. Dr J. Anderson † in particular informs us, that it "begins to send out its flower-stems in the spring, nearly about the same time with the common turnip; but that the root, in consequence of that change of state, suffers very little alteration. I continued to use these turnips at my table every day till towards the middle of May; and had I never gone into the garden myself, I should not even then have suspected, from the taste or appearance of the bulb itself, that it had been shot at all. The stems, however, at the season I gave over using them, were from four to five feet high, and in full flower. I should have continued the experiment longer, had not the quantity I had left for that purpose been exhausted, and a few only left for seed.

"This experiment, however, fully proves, that this kind of turnip may be employed as a succulent food for cattle till the middle of May at least, in an ordinary year; and I have not the smallest doubt but it will continue perfectly good for that purpose till the end of May in any season; at which time grass and other spring-crops can easily be had for bringing beasts forward in flesh. I can therefore, without hesitation, recommend this plant to the farmer as a most valuable spring-feeding for cattle and sheep; and for this purpose, I think no wise farmer should be without a proportion of this kind of turnip to succeed the other sorts after they fail. The profitable method of consuming it, where it is to be kept very late, is, I am convinced, to cut off the tops with a scythe or sickle when from one foot to eighteen inches high, to induce it to send out fresh stems, that will continue soft and succulent to the end; whereas, without this process, the stems would become starchy and useless.

"I cannot, however, recommend this kind of turnip, from what I have yet seen, as a general crop; because I think it probable, that unless in particular circumstances, the common field-turnips grow to a much larger size, and afford upon the whole a more weighty crop. These, there, should still continue to be cultivated for winter use, the other being reserved only for spring consumption.

"Experiments are still wanting to ascertain with certainty the peculiar soil and culture that best agree with

VOL. VIII. Part II.

this plant; but from the few observations I have hitherto had an opportunity of making upon it, it seems to me probable, that it thrives better, and grows to a larger size on damp clayey soil, than on light sandy land. But I would not wish to be understood as here speaking positively; I merely throw it out as a hint for future observation: on spongy soil it prospers.

"Though the uses of this as a garden plant are of much smaller consequence than those above-specified, it may not be improper to remark, that its leaves form a very sweet kind of greens at any time; and merely for the sake of the experiment, I caused some of these to be picked off the stems of the plants coming to seed, on the 4th of June, the king's birth-day, which, on being readied, were found perfectly sweet, without the smallest tendency to bitterness, which most, if not all other kinds of greens that have been hitherto cultivated are known to acquire after their stems are considerably advanced; no family, therefore, can ever be at a loss for greens when they have any of this plant in seed.

"A root of this kind of turnip was taken up this day (June 15th); the seed stalks were firm and woody, the pods full formed, and in some of them the seeds were nearly ripe. The root, however, was as soft and succulent as at any former period of its growth; nor was the skin, as I expected, hard or woody. It was made ready and brought to the table; some persons there thought the taste as good, if not better, than at any former period of its growth; but I myself, perhaps through prejudice, thought it had not quite so high a relish as in winter: At any rate, however, there can be no doubt, that if ever it could be necessary, it might, even now, be employed very properly as a feeding for cattle."

SECT. X. *Turnip-Cabbage.*

THIS plant is as yet but little known. The seed is said to have been brought from the Cape of Good Hope by Mr Hastings, where it is very common as well as in Holland. It has also had an existence in Britain for many years, though not generally known. It has a much greater affinity to the cabbage than to the turnip; and is very hardy, bearing the winter as well, if not better, than common brocoli, and may therefore be considered as a valuable acquisition to the kitchen-garden as well as for cattle. The best time for sowing it for the garden is the end of May or beginning of June, though none of the plants have ever been observed to run to seed though sown ever so early. Even though sown in August at the cauliflower season, the greater part stood throughout the following summer, and did not seed till the second spring. The plants require nearly the same management with brocoli as to distance, transplanting, &c. and are usually most esteemed when young, and about the size of a moderate garden turnip; those sown in June will continue all winter. The bulb must be stripped clean of its thick fibrous rind; after which it may be used as a common turnip. The crown or sprout is very good, but especially in the spring, when they begin to run to seed. Mr Broughton, from whose account in the Bath Papers, vol. v. this article is taken, thinks that the turnip-cabbage is more nutritious than the common turnip. The largest bulb he measured was 23 inches

Turnip-
Cabbage.

109
Method of
cultivation.

5 C

circum.

Cabbage.

circumference; but the thickness of the rind is so great, that some farmers imagined that the bulb would be too hard for sheep. The objection, however, was obviated by Mr Broughton, who gave some of the oldest and toughest bulbs to his sheep, and found that they not only penetrated through the rind, but even devoured the greatest part of it.

SECT. XI. *Cabbage.*

CABBAGE has been recommended by long experience as an excellent food for cattle; it uses as part of human food are also well known. In a paper already quoted from those of the Bath Society, Scotch cabbages are compared, as to their utility in feeding cattle, with turnips, turnip-rooted cabbage, and carrots. In this trial the cabbages stand next in value to the carrots; and they are recommended as not liable to be affected by frost, if they be of the true flat-topped firm kind. Fifty-four tons have been raised upon an acre of ground not worth more than 12 shillings. There is likewise an advantage attending the feeding of cattle with cabbages, viz. that their dung is more in proportion than when fed with turnips or with hay; the former going off more by urine, and the latter having too little moisture. They also impoverish the ground much less than grain. Mr Billingsley accounts 46 tons per acre a greater crop than he ever read of; but Mr Vagg, in the 4th volume of Bath Papers, gives an account of a crop for which he received a premium from the Society, which was much superior to that of Mr Billingsley. Its extent was 12 acres; the produce of the worst was 42, and of the best 68 tons. They were manured with a compost of lime, weeds, and earth, that lay under the hedges round the field, and a layer of dung, all mixed and turned together. About 25 cart-loads of this were spread upon an acre with the usual ploughing given to a common summer-fallow; but this, he says, "admitting such crop to exhaust the manure in some degree by its growth, an ample restoration will be made by its refuse ploughed in, and by the stirring and cleaning of the ground. The whole expence of an acre, exclusive of the rent, according to Mr Vagg's calculation, amounts to L. 1 : 14 : 1, only four ounces of seed being requisite for an acre. The 12 acres, producing as above mentioned, would feed 45 oxen, and upwards of 60 sheep, for three months; improving them as much as the grass in the best months of the year, May, June, and July. He recommends sowing the seed about the middle of August, and transplanting the young cabbages where they may be sheltered from the frost; and to the neglect of this he ascribes the partial failure, or at least inferiority of one part of his ground in the crop just mentioned, the young plants not being removed till near midsummer, and then in so dry a time, that they were almost scorched up.

In the Farmer's Magazine, vol. ii. p. 217. we have several pertinent remarks upon the culture of this useful plant, particularly with regard to watering. "It is a rule (says this correspondent) never to water the plants, let the season be as dry as it may; insinuating that it is entirely useless. If the land is in fine tilth and well dunged, this may be right, as the expence must be considerable; but it is probable, in very dry seasons, when the new set plants have nothing but a

burning sun on them, that watering would save vast numbers, and might very well answer the expence, if a pond is near, and the work done with a water-cart." He takes notice also of another use of cabbages, which has not met with the attention it merits, viz. the planting of lands where turnips have failed. A late sown crop of these seldom turns to any account; but cabbages planted on the ground without any ploughing would prove very beneficial for sheep late in the spring; in all probability (unless on light, sandy, or limestone soils) of greater value than the turnips, had they succeeded.

Mr Marshall observes, that in the Midland district, a valuable sort of large green cabbage "is propagated, if not raised, by Mr Bakewell. who is not more celebrated for his breed of rams than for his breed of cabbages. Great care is observed here in raising the seed, being careful to suffer no other variety of the brassica tribe to blow near seed-cabbages; by which means they are kept true to their kind. To this end, it is said, that some plant them in a piece of wheat; a good method, provided the seed in that situation can be preserved from birds."

The advantage of having large cabbages is that of being able to plant them wide enough from each other, to admit of their being cleaned with the plough, and yet to afford a full crop. The proper distance depends in some measure on the natural size of the species and the strength of the soil; the thinner they stand, the larger they will grow: but our author is of opinion, that cabbages, as well as turnips, are frequently set out too thin. Four feet by two and an half, according to Mr Marshall, are a full distance for large cabbages on a rich soil.

SECT. XII. *Parsnips.*

THESE, though little used in Britain, are highly esteemed in France and some of our neighbouring islands as food for cattle. In Brittany particularly, they are thought to be little inferior in this respect to wheat; and cows fed with them are said to give as much milk, and of as good quality, as in the summer-months. It is also very much commended for swine which rear young pigs, and for fattening the swine themselves. The author of this paper also recommends a method of determining the nutritive qualities of plants by the quantity of mucilage they contain; which may be known by boiling them in water, and then evaporating the decoction: the parsnip, he supposes, would yield a greater quantity of mucilage than either carrots or potatoes.

"To cultivate this root (says Mr Hazard) so as to make it advantageous to the farmer, it will be right to sow the seed in the autumn immediately after it is ripe; by which means the plants will appear early the following spring, and get strong before the weeds can rise to injure them. Neither the seeds nor young plants are ever materially injured by frosts; on which account, as well as many others, the autumn is preferable to the spring sowing. The best soil for them is a rich deep loam, and next to this sand. They will thrive well in a black gritty soil, but not in stone-brash, gravel, or clay; and they are always largest in the deepest earth. If the soil be proper, they do not require much manure. Mr Hazard obtained a very good

Parfnips. good crop for three years upon the same piece of ground without using any; but when he laid on about 40 cart loads of sand per acre upon a stiff loam, and ploughed it in, he found it answer very well; whence he concludes, that a mixture of soils may be proper for this root. The seed may be sown in drills at about 18 inches distance from one another, that the plants may be the more conveniently hand or horse hoed; and they will be more luxuriant if they undergo a second hoeing, and are carefully earthed, so as not to cover the leaves. Such as have not ground to spare, or cannot get it in proper condition in autumn, may at that time sow a plot in their garden, and transplant from thence in the latter end of April, or early in the month of May following. The plants must be carefully drawn, and the ground well pulverised by harrowing and rolling; after which a furrow should be opened with the plough about six or eight inches deep, in which the plants should be regularly laid at the distance of about ten inches from each other, taking care not to let the root be bent, but for the plant to stand perpendicular after the earth is closed about it, which ought to be done immediately by means of persons who should for this purpose follow the planter with a hoe. Another furrow must be opened about 18 inches from the former, in the same direction, and planted as before; and so on in like manner until all the plants are deposited, or the field be completely cropped; and when the weeds appear, hoeing will be necessary, and it will afterwards be proper to earth them; but if the leaves of the plants be covered with earth, the roots will be injured. **Parfnips** ought not to be planted by dibbling, as the ground thus becomes so bound, as seldom to admit the small lateral fibres with which these roots abound to fix in the earth, by which they are prevented from expanding themselves, and never attain a proper size. When circumstances are properly attended to, there is little doubt that a crop of parfnips would answer much better than a crop of carrots.

They are equal, if not superior, in fattening pigs, as they make their flesh whiter, and the animals themselves are more fond of these roots than of carrots. Horses eat them greedily when clean washed and sliced among bran, and thrive very well upon them; and black cattle are said likewise to approve of them.

THE foregoing are the principal vegetables which have as yet been recommended, or which experience has determined to be proper, to be raised as food for men or for cattle.

One or two other plants may be just noticed, which have lately fallen under the observation of those who apply themselves to the study of husbandry, viz. the *root of scarcity*, and what are called *mowing cabbages*. Concerning the latter, no experiments have yet been made to determine sufficiently their properties and value. They are mentioned in the Bath Papers † by Sir John Beevor, who had a small parcel of seed sent him; which he sowed in spring, and several plants were produced. Some of these were cut down three times, and grew into heads again so speedily, “that (says he) had I had leisure to have attended to them, I doubt not but that the cuttings might have been repeated; but as there is never on my farm any want of fresh vegetable food for cattle in the summer, unless I can find them continue to vegetate in like manner during the winter (which mine have not done) or very early in the spring, I think they will not prove to me, or any one under the like circumstances, an object of much value.—As to the *root of scarcity*, we have nothing to add to what has been said on it under AGRICULTURE, n° 52. Notwithstanding a great number of experiments, it still appears uncertain whether it be really useful or not.

With regard to *Grasses*, the most useful species have been described under the article GRASS, and the cultivation of them so fully explained under AGRICULTURE, as to require no further enlargement here.

PART II. CULTIVATION OF VEGETABLES more properly ARTICLES OF COMMERCE.

THESE in general are such as cannot be used for food; and are principally flax, hemp, rape, hops, and timber of various kinds; and of each of these we shall treat particularly in the following sections.

SECT. I. Of Flax and Hemp.

THIS plant is cultivated not only with a view to the common purposes of making linen, but for the sake of its seed also; and thus forms a most extensive article of commerce, all the oil used by painters, at least for common purposes, being extracted from this seed. The cake which remains after the extraction of the oil is in some places used as a manure, and in others sold for fattening of cattle. In the Vale of Gloucester, Mr Marshall informs us that it is, next to hay, the main article of stall-fattening; though the price is now become so great, that it probably now leaves little or no profit to the consumer, having within a few years risen from three guineas to six and six and an half, and the lowest price being five guineas per ton; and even this is lower than it was lately. Hence some individuals have been induced to try the effect of linseed itself boiled to a jelly, and mixed with flour, bran, or

chaff, with good success, as Mr Marshall has been informed; and even the oil itself has been tried for the same purpose in Herefordshire. Though this plant is in universal culture over the whole kingdom, yet it appears by the vast quantity imported, that by far too little ground is employed in that way. As Mr Marshall takes notice of its culture only in the county of Yorkshire, it probably does not make any great part of the husbandry of the other countries of which he treats; and even in Yorkshire he tells us, that its cultivation is confined to a few districts. The kind cultivated there is that called “blea line,” or the blue or lead-coloured flax, and this requires a rich dry soil for its cultivation. A deep, fat, sandy loam is perhaps the only soil on which it can be cultivated with advantage. If sown upon old corn-land, it ought to be well cleaned from weeds, and rendered perfectly friable by a summer-fallow. Manure is seldom or ever set on for a line crop; and the soil process consists generally of a single plowing. The seed-time is the month of May, but much depends on the state of the soil at the time of sowing. “It should neither be wet nor dry; and the surface ought to be made as fine as that of a garden bed. Not a clod of the size of an egg should remain

main unbroken." Two bushels of seed are usually sown upon an acre: the surface, after being harrowed, is sometimes raked with garden or hay-rakes; and the operation would be still more complete if the clods and other obstructions, which cannot be easily removed, were drawn into the interfurrows. A light hand-roller used between the final raking and harrowing would much assist this operation. The chief requisite during the time of vegetation is weeding, which ought to be performed with the utmost care; and for this reason it is particularly requisite that the ground should be previously cleansed as well as possible, otherwise the expence of weeding becomes too great to be borne, or the crop must be considerably injured. It is an irreparable injury, if, through a dry season, the plants come up in two crops; or if by accident or mismanagement they be too thin. The goodness of the crop depends on its running up with a single stalk without branches: for wherever it ramifies, there the length of the line terminates; and this ramification is the consequence of its having too much room at the root, or getting above the plants which surround it. The branches are never of any use, being unavoidably worked off in dressing; and the stem itself, unless it bear a due proportion to the length of the crop, is likewise worked off among the refuse. This ramification of the flax will readily be occasioned by clods on the ground when sown. A second crop is very seldom attended with any profit; for being overgrown with the spreading plants of the first crop, it remains weak and short, and at pulling time is left to rot upon the land.

Flax is injured not only by drought but by frost, and is sometimes attacked, even when got five or six inches high, by a small white slug, which strips off the leaves to the top, and the stalks bending with their weight are thus sometimes drawn into the ground. Hence, if the crop does not promise fair at weeding time, our author advises not to bestow further labour and expence upon it. A crop of turnips or rape will generally pay much better than such a crop of flax. The time of flax-harvest in Yorkshire is generally in the latter end of July or beginning of August.

On the whole, our author remarks, that "the goodness of the crop depends in some measure upon its length; and this upon its evenness and closeness upon the ground. Three feet high is a good length, and the thickness of a crow's quill a good thickness. A fine stalk affords more line and fewer shivers than a thick one. A tall thick set crop is therefore desirable. But unless the land be good, a thick crop cannot attain a sufficient length of stem. Hence the folly of sowing flax on land which is unfit for it. Nevertheless, with a suitable soil, a sufficiency of seed evenly distributed, and a favourable season, flax may turn out a very profitable crop. The flax-crop, however, has its disadvantages: it interferes with harvest, and is generally believed to be a great exhauster of the soil, especially when its seed is suffered to ripen. Its cultivation ought therefore to be confined to rich grass-land districts, where harvest is a secondary object, and where its exhaustion may be rather favourable than hurtful to succeeding arable crops, by checking the too great rankness of rich fresh broken ground.

In the 5th volume of Bath-Papers, Mr Bartley, near Bristol, gives an account of the expences and produce

of five acres of flax cultivated on a rich loamy sand. The total expence was 42 l. 13 s. 4 d. the produce was ten packs of flax at 5 l. 5 s. value 52 l. 10 s. 35 bushels of linseed at 5 s. value 3 l. 15 s. the net profit therefore was 18 l. 11 s. 8 d. or 4 l. 13 s. 4 d. per acre. This gentleman is of opinion that flax-growers ought to make it their staple article, and consider the other parts of their farm as in subserviency to it.

In the 2d volume of Bath-Papers, a Dorsetshire gentleman, who writes on the culture of hemp and flax, gives an account somewhat different from that of Mr Marshall. Instead of *exhausting* crops, he maintains that they are both *ameliorating* crops, if cut without feeding; and as the best crops of both are raised from foreign seed, he is of opinion that there is little occasion for raising it in this country. A crop of hemp, he informs us, prepares the land for flax, and is therefore clear gain to the farmer. "That these plants impoverish the soil," he repeats, "is a mere vulgar notion, devoid of all truth.—The best historical relations, and the verbal accounts of honest ingenious planters, concur in declaring it to be a vain prejudice, unsupported by any authority; and that these crops really meliorate and improve the soil." He is likewise of opinion, that the growth of hemp and flax is not necessarily confined to rich soils, but that they may be cultivated with profit also upon poor sandy ground, if a little expence be laid out in manuring it. "Spalding-moor in Lincolnshire is a barren sand; and yet with proper care and culture it produces the best hemp in England, and in large quantities. In the isle of Asholme, in the same county, equal quantities are produced; for the culture and management of it is the principal employ of the inhabitants; and, according to Leland, it was so in the reign of Henry VIII. In Marshland the soil is a clay or strong warp, thrown up by the river Ouze, and of such a quality, that it cracks with the heat of the sun, till a hand may be put into the chinks; yet if it be once covered with the hemp or flax before the heats come on, the ground will not crack that summer. When the land is sandy, they first sow it with barley, and the following spring they manure the stubble with horse or cow dung, and plough it under. Then they sow their hemp or flax, and harrow it in with a light harrow, having short teeth. A good crop destroys all the weeds, and makes it a fine fallow for flax in the spring. As soon as the flax is pulled, they prepare the ground for wheat. Lime, marl, and the mud of ponds, is an excellent compost for hemp-lands."

Our author takes notice of the vast quantity of flax and hemp, not less than 11,000 tons imported in the year 1763 into Britain; and complains that it is not raised in the island, which he thinks might be done, though it would require 60,000 acres for the purpose. He observes, that the greater part of those rich marshy lands lying to the west of Mendip hills are very proper for the cultivation of hemp and flax; and if laid out in this manner could not fail of turning out highly advantageous both to the landholders and the public at large. "The vast quantities of hemp and flax (says he) which have been raised on lands of the same kind in Lincolnshire marshes, and the fens of the Isle of Ely and Huntingdonshire, are a full proof of the truth of my assertion. Many hundreds of acres in the above mentioned places, which, for pasturage or grazing, were not

Cole Seed. not worth more than 20 or 25 shillings per acre, have been readily let at 4l. the first year, 3l. the second, and 2l. the third. The reason of this supposed declining value of land, in proportion to the number of years sown with flax, is, that it is usual with them to seed it for the purpose of making oil, that being the principal cause of the land being thereby impoverished.

SECT. II. *Rape or Cole Seed.*

Bath Papers, vol. iv.

126
Advantage of cultivating rape-seed.

127
Of cutting and thrashing the rape-seed.

128
Of sowing it.

129
Transplanting recommended.

130
Sheep may be fed in the spring with rape.

THIS, as well as linseed, is cultivated for the purpose of making oil, and will grow almost any where. Mr Hazard informs us, that in the north of England the farmers pare and burn their pasture lands, and then sow them with rape after one ploughing; the crop commonly standing for seed, which will bring from 25l. to 30l. per last (80 bushels.) Poor clay, or stone-brash land, will frequently produce from 12 to 16 or 18 bushels per acre, and almost any fresh or virgin earth will yield one plentiful crop; so that many in the northern counties have been raised, by cultivating this seed, from poverty to the greatest affluence. The seed is ripe in July or the beginning of August; and the threshing of it out is conducted with the greatest mirth and jollity.

The rape being fully ripe, is first cut with sickles, and then laid thin upon the ground to dry; and when in proper condition for threshing, the neighbours are invited, who readily contribute their assistance. The threshing is performed on a large cloth in the middle of the field, and the seed put into sacks and carried home. It does not admit of being carried from the field in the pod in order to be threshed at home, and therefore the operation is always performed in the field; and by the number of assistants procured on this occasion, a field of 20 acres is frequently threshed out in one day. The straw is burnt for the sake of its alkali, the ashes being said to equal the best kind of those imported from abroad.

The proper time for sowing rape is the month of June; and the land should, previous to the sowing, be twice well ploughed. About two pounds of seed are sufficient for an acre; and, according to our author, it should be cast upon the ground with only the thumb and two fore-fingers; for if it be cast with all the fingers, it will come up in patches. If the plants come up too thick, a pair of light harrows should be drawn along the field length-ways and cross-ways; by which means the plants will be equally thinned; and when the plants which the harrows have pulled up are withered, the ground should be rolled. A few days after the plants may be set out with a hoe, allowing 16 or 18 inches distance betwixt every two plants.

Mr Hazard strongly recommends the transplanting of rape, having experienced the good effects of it himself. A rood of ground, sown in June, will produce as many plants as are sufficient for 10 acres; which may be planted out upon ground that has previously borne a crop of wheat, provided the wheat be harvested by the middle of August. One ploughing will be sufficient for these plants; the best of which should be selected from the seed-plot, and planted in rows two feet asunder and 16 inches apart in the rows. As rape is an excellent food for sheep, they may be allowed to feed upon it in the spring; or the leaves might be gathered, and given to oxen or young cattle: fresh

leaves would sprout again from the same stalks, which in like manner might be fed off by ewes and lambs in time enough to plough the land for a crop of barley and oats. Planting rape in the beginning of July, however, would be most advantageous for the crop itself, as the leaves might then be fed off in the autumn, and new ones would appear in the spring. Our author discommends the practice of sowing rape with turnips, as the crops injure one another. "Those who look for an immediate profit (says he), will undoubtedly cultivate rape for seed; but perhaps it may answer better in the end to feed it with sheep: the fat ones might cull it over first, and afterwards the lean or store-sheep might follow them, and be folded thereon: if this is done in autumn season, the land will be in good heart to carry a crop of wheat; or where the rape is fed off in the spring, a crop of barley might follow. In either case rape is profitable to the cultivator; and when it is planted, and well earthed round the stems, it will endure the severest winter; but the same cannot be advanced in favour of that which is sown broadcast.

SECT. III. *Coriander Seed.*

THIS is used in large quantities by distillers, druggists, and confectioners, and might be a considerable object to such farmers as live in the neighbourhood of great towns; but the price is very variable, viz. from 16s. to 42s. per cwt. In the 4th volume of Bath Papers, Mr Bartley gives an account of an experiment made on this seed, which proved very successful. Ten peaches of good sandy loam were sown with coriander on the 23d of March 1783. Three pounds of seed were sufficient for this spot; and the whole expence amounted only to 5s. 10d. The produce was 87 pounds of seed, which, valued at 3d. yielded a profit of 15s. 11d. or 15l. 18s. 4d. per acre. He afterwards made several other experiments on a larger scale; but none of the crops turned out so well, though all of them afforded a good profit.

131
Mr Bartley's experiment.

SECT. IV. *Canary Seed.*

THIS is cultivated in large quantity in the Isle of Thanet, where it is said they have frequently 20 bushels to an acre. Mr Bartley, in the month of March 1783, sowed half an acre of ground, the soil a mixture of loam and clay, but had only eight bushels and an half, or 17 bushels per acre. With this produce, however, he had a profit of 4l. 2s. 3d. per acre.

SECT. V. *Woad.*

THE use of this in dyeing is well known, and the consumption is so great, that the raising of the plant might undoubtedly be an object to an husbandman, provided he could get it properly manufactured for the dyers, and could overcome their prejudices. At present, the growing of this plant is in a manner monopolized by some people in particular places, particularly at Keynsham near Bristol in England. Mr Bartley informs us, that in a conversation he had with these growers, the latter asserted, that the growth of woad was peculiar to their soil and situation. The soil about this place is a blackish heavy mould, with a considerable

132
Woad easily cultivated.

Coriander Seed, &c.

Hops.

able proportion of clay; but works freely: that of Brislington, where Mr Bartley resides, an hazal, sandy loam; nevertheless, having sowed half an acre of this soil with woad-feed, it throve so well, that he never saw a better crop at Keynsham. Having no apparatus, however, or knowledge of the manufacture, he suffered it to run to seed, learning only from the experiment, that woad is very easily cultivated, and that the only difficulty is the preparing it for the market.

SECT. VI. *Hops.*

133
Hops for-
bid by act
of parlia-
ment.

THE uses of these, as an ingredient in malt-liquors, are well known. Formerly, however, they were supposed to possess such deleterious qualities, that the use of them was forbid by act of parliament in the reign of James VI. But though this act was never repealed, it does not appear that much regard was ever paid to it, as the use of hops has still continued, and is found not to be attended with any bad effects on the human constitution. The only question, therefore, is, How far the raising a crop of them may be profitable to an husbandman? and indeed this seems to be very doubtful.

† *Annals of
Agriculture,*

134
Expence of
cultivating
them at
Castle Hed-
ingham.

Mr Arthur Young, in a fortnight's tour through Kent and Essex, informs us† that at Castle Hedingham he was told by a Mr Rogers, who had a considerable hop plantation, that four acres of hop-ground cost him upwards of 120l. and that the usual expences of laying out an acre of ground in this way amounted to 34l. 6s. By a calculation of the expences of an acre in Kent, it appeared that the money sunk to plant an acre there amounted to 32l. 8s. 6d.; that the annual expence was 23l. and the profit no more than 1l. 8s. 1d. In another place, he was informed by a Mr Potter, who cultivated great quantities of hops, that if it were not for some extraordinary crops which occurred now and then, nobody would plant them. In Essex, the expences of an hop-plantation are still greater than those we have yet mentioned; an acre many years ago requiring 75l. to lay it out on hops, and now not less than 100l. the annual expence being estimated at 31l. 1s. while the produce commonly does not exceed 32l.

135
In Essex.

In the neighbourhood of Stow-market in this county, Mr Young informs us, there are about 200 acres planted with hops, but "18 or 20 are grubbed up within two years, owing to the badness of the times." Here they are planted on a black loose moor, very wet and boggy; and the more wet the better for the crop, especially if the gravel, which constitutes the bottom, be not more than three feet from the surface. In preparing the ground for hops, it is formed into beds 16 feet wide, separated from each other by trenches. In these beds they make holes six feet asunder, and about 12 inches diameter, three rows upon a bed. Into each hole they put about half a peck of very rotten dung or rich compost; scatter earth upon it, and plant seven sets in each; drawing earth enough to them afterwards to form something of an hillock. A hop garden, Mr Young informs us, "will last almost for ever, by renewing the hills that fail, to the amount of about a score annually; but it is reckoned better to grub up and new-plant it every 20 or 25 years."

In this volume of the *Annals*, Mr Young informs

us, that "one profit of hop-land is that of breaking it up. Mr Potter grubbed up one garden, which failing, he ploughed and sowed barley, the crop great; then mazagan beans, two acres of which produced 16 quarters and five bushels. He then sowed it with wheat, which produced 13 quarters and four bushels and an half; but since that time the crops have not been greater than common. The same gentleman has had 10 quarters of oats after wheat." In the ninth volume of the same work, however, we have an account of an experiment by Mr Le Bland of Sittingbourn in Kent, of grubbing up 12 acres of hop-ground, which was not attended with any remarkable success. Part of the hops were grubbed up in the year 1781, and mazagan beans sown in their stead; but by reason of the seed being bad, and the dry summer, the crop turned out very indifferent. Next year the remainder of the hops were grubbed up, and the whole 12 acres sown with wheat; but still the crop turned out very bad, owing to the wet summer of that year. It was next planted with potatoes, which turned out well; and ever since that time the crops have been good. This gentleman informs us, that the person who had the hop-ground above mentioned did not lose less by it than 1500l.

Cultivation

136
Profit of
breaking
up hop-
land prece-
rious.

The culture of hops seems to be confined in a great measure to the southern counties of England; for Mr Marshall mentions it as a matter of surprise, that in Norfolk he saw a "tolerably large hop garden." The proprietor informed him, that three or four years before there had been 10 acres of hops in the parish (Blowfield) where he resided; which was more than could be collected in all the rest of the county; but at that time there were not above five; and the culture was daily declining, as the crops, owing to the low price of the commodity, did not defray the expence.

137
Culture of
hops in
Norfolk on
the decline.

From all this it appears, that hops are perhaps the most uncertain and precarious crop on which the husbandman can bestow his labour. Mr Young is of opinion, that some improvement in the culture is necessary; but he does not mention any, excepting that of planting them in espaliers. This method was recommended both by Mr Rogers and Mr Potter above-mentioned. The former took the hint from observing, that a plant which had been blown down, and afterwards shot out horizontally, always produced a greater quantity than those which grew upright. He also remarks, that hops which are late picked carry more next year than such as are picked early; for which reason he recommends the late picking. The only reason for picking early is, that the hops appear much more beautiful than the others.

SECT. VII. *Cultivation of Fruit.*

IN Herefordshire and Gloucestershire the cultivation of fruit for the purpose of making a liquor from the juice, forms a principal part of their husbandry. In Devonshire also considerable quantities of this kind of liquor are made, though much less than in the two counties above-mentioned.

The fruits cultivated in Herefordshire and Gloucestershire are, the apple, the pear, and the cherry. From the two first are made the liquors named *cyder* and *per-ry*; but though it is probable that a liquor of some value might be made from cherries also, it does not appear

pear to have ever been attempted. Mr Marshall remarks, that nature has furnished only one species of pears and apples, viz. the common crab of the woods and hedges, and the wild pear, which is likewise pretty common. The varieties of these fruits are entirely artificial, being produced not by seed, but by a certain mode of culture; whence it is the business of those who wish to improve fruit therefore, to catch at superior accidental varieties; and having raised them by cultivation to the highest perfection of which they are capable, to keep them in that state by artificial propagation. Mr Marshall, however, observes, that it is impossible to make varieties of fruit altogether permanent, though their duration depends much upon management. "A time arrives (says he) when they can no longer be propagated with success. All the old fruits which raised the fame of the liquors of this country are now lost, or so far on the decline as to be deemed irrecoverable. The *redstreak* is given up; the celebrated *stir-apple* is going off; and the *squash-pear*, which has probably furnished this country with more *champaign* than was ever imported into it, can no longer be got to flourish: the stocks canker, and are unproductive. In Yorkshire similar circumstances have taken place: several old fruits which were productive within my own recollection are lost; the stocks cankered, and the trees would no longer come to bear."

Our author controverts the common notion among orchard-men, that the decline of the old fruits is owing to a want of fresh grafts from abroad, particularly from Normandy, from whence it is supposed that apples were originally imported into this country. Mr Marshall, however, thinks, that these original kinds have been long since lost, and that the numerous varieties of which we are now possessed were raised from seed in this country. He also informs us, that at Ledbury he was shown a Normandy apple-tree, which, with many others of the same kind, had been imported immediately from France. He found it, however, to be no other than the *bitter-sweet*, which he had seen growing as a neglected wilding in an English hedge.

The process of raising new varieties of apples, according to Mr Marshall, is simple and easy. "Elect (says he) among the native species individuals of the highest flavour; sow the seeds in a highly enriched feed-bed. When new varieties, or the improvement of old ones, are the objects, it may perhaps be eligible to use a frame or stove; but where the preservation of the ordinary varieties only is wanted, an ordinary loamy soil will be sufficient. At any rate, it ought to be perfectly clean at least from root weeds, and should be double dug from a foot to 18 inches deep.—The surface being levelled and raked fine, the seeds ought to be scattered on about an inch asunder, and covered about half an inch deep with some of the finest mould previously raked off the bed for that purpose. During summer the young plants should be kept perfectly free from weeds, and may be taken up for transplantation the ensuing winter; or if not very thick in the feed-bed, they may remain in it till the second winter.

The nursery ground ought also to be enriched, and double dug to the depth of 14 inches at least; though 18 or 20 are preferable. The seedling plants ought to be sorted agreeably to the strength of their roots, that they may rise evenly together. The top, or downward

roots should be taken off, and the longer side rootlets shortened. The young trees should then be planted in rows three feet asunder, and from 15 to 18 inches distant in the rows; taking care not to cramp the roots, but to lead them evenly and horizontally among the mould. If they be intended merely for stocks to be grafted, they may remain in this situation until they be large enough to be planted out; though, in strict management, they ought to be re-transplanted two years before their being transferred into the orchard, "in fresh but unmanured double-dug ground, a quincunx four feet apart every way." In this second transplantation, as well as in the first, the branches of the root ought not to be left too long, but to be shortened in such a manner as to induce them to form a globular root, sufficiently small to be removed with the plant; yet sufficiently large to give it firmness and vigour in the plantation.

Having proceeded in this manner with the feed-bed, our author gives the following directions. "Select from among the seedlings the plants whose wood and leaves wear the most *apple-like* appearance. Transplant these into a rich deep soil in a genial situation, letting them remain in this nursery until they begin to bear. With the seeds of the fairest, richest, and best flavoured fruit repeat this process; and at the same time, or in due season, engraft the wood which produced this fruit on that of the richest, sweetest, best flavoured apple: repeating this operation, and transferring the subject under improvement from one tree and sort to another, as richness, flavour, or firmness may require; continuing this double mode of improvement until the desired fruit be obtained. There has, no doubt, been a period when the improvement of the apple and pear was attended to in this country; and should not the same spirit of improvement revive, it is probable that the country will, in a course of years, be left destitute of valuable kinds of these two species of fruit; which, though they may in some degree be deemed objects of luxury, long custom seems to have ranked among the necessities of life."

In the fourth volume of Bath Papers, Mr Grimwood supposes the degeneracy of apples to be rather imaginary than real. He says, that the evil complained of "is not a real decline in the quality of the fruit, but in the tree; owing either to want of health, the season, soil, mode of planting, or the stock they are grafted on, being too often raised from the seed of apples in the same place or county.—I have not a doubt in my own mind, but that the trees which are grafted on the stocks raised from the apple-pips are more tender than those grafted on the real crab-stock; and the seasons in this country have, for many years past, been unfavourable for fruits, which add much to the supposed degeneracy of the apple. It is my opinion, that if planters of orchards would procure the trees grafted on real crab-stocks from a distant country, they would find their account in so doing much overbalance the extra expence of charge and carriage.

In the same volume, Mr Edmund Gillingwater assigns as a reason for the degeneracy of apples the mixture of various farina, from the orchards being too near each other. In consequence of this notion, he also thinks that the old and best kinds of apple-tree are not lost, but only corrupted from being

Cultivation
of fruit.

planted too near bad neighbours: "Remove them (says he) to a situation where they are not exposed to this inconvenience, and they will immediately recover their former excellency." This theory, however, is not supported by a single experiment.

146
Mr Samuel's opinion
of the method of re-
covering
the best
fruit.

In this volume also Mr Richard Samuel expresses his concern at the "present neglect of orchards, where the old trees are decaying, without proper provision being made for the succeeding age: for if a farmer plants fresh trees (which does not frequently happen), there is seldom any care taken to propagate the better sorts, as his grafts are usually taken promiscuously from any ordinary kind most easily procured in the neighbourhood." His remedy is to collect grafts from the best trees; by which means he supposes that the superior kinds of fruit would soon be recovered. To a care of this kind he attributes the superiority of the fruit in the neighbourhood of great towns to that in other places.

147
Cultiva-
tion, &c.
of fruit-
trees.

With regard to the method of cultivating fruit-trees, it is only necessary to add, that while they remain in the nursery, the intervals betwixt them may be occupied by such kitchen-stuff as will not crowd or overshadow the plants; keeping the rows in the mean time perfectly free from weeds. In pruning them, the leader should be particularly attended to. If it shoot double, the weaker of the contending branches should be taken off; but if the leader be lost, and not easily recoverable, the plant should be cut down to within a hand's breadth of the soil, and a fresh stem trained. The undermost boughs should be taken off by degrees, going over the plants every winter; but taking care to preserve heads of sufficient magnitude not to draw the stems up too tall, which would make them feeble in the lower part. The stems in Herefordshire are trained to six feet high; but our author prefers seven, or even half a rod in height. A tall stemmed tree is much less injurious to what grows below it than a low-headed one, which is itself in danger of being hurt, at the same time that it hurts the crop under it. The thickness of the stem ought to be in proportion to its height; for which reason a tall stock ought to remain longer in the nursery than a low one. The usual size at which they are planted out in Herefordshire is from four to six inches girth at three feet high; which size, with proper management, they will reach in seven or eight years. The price of these stocks in Herefordshire is 18d. each. Our author met with one instance of crabstocks being gathered in the woods with a good prospect of success.

148
Method of
managing
the ground
of orchards
in Here-
fordshire
and Glou-
cestershire.

In Herefordshire it is common to have the ground of the orchards in tillage, and in Gloucestershire in grass; which Mr Marshall supposes to be owing to the difference betwixt the soil of the two counties; that of Herefordshire being generally arable, and Gloucestershire grass land. Trees, however, are very destructive, not only to a crop of corn, but to clover and turnips; though tillage is favourable to fruit-trees in general, especially when young. In grass grounds their progress is comparatively slow, for want of the earth being stirred about them, and by being injured by the cattle, especially when low-headed and drooping. After they begin to bear, cattle ought by all means to be kept away from them, as they not only destroy all the fruit within their reach, but the fruit itself is dangerous to the cattle, being apt to stick in their throats and choak

Nº 160.

them. These inconveniences may be avoided, by eating the fruit grounds bare before the gathering season, and keeping the boughs out of the way of the cattle: but Mr Marshall is of opinion, that it is wrong to plant orchards in grass land. "Let them (says he) lay their old orchards to grass: and if they plant, break up their young orchards to arable. This will be changing the course of husbandry, and be at once beneficial to the land and the trees.

Our author complains very much of the indolent and careless method in which the Herefordshire and Gloucestershire farmers manage their orchards. The natural enemies of fruit-trees (he says) are, 1. A redundancy of wood. 2. The mistletoe. 3. Moss. 4. Spring frosts. 5. Blights. 6. Insects. 7. An excess of fruit. 8. Old age.

1. A redundancy of wood is prejudicial, by reason of the barren branches depriving those which bear fruit of the nourishment which ought to belong to them. A multitude of branches also give the winds such an additional power over the tree, that it is in perpetual danger of being overthrown by them: trees are likewise thus injured by the damps and want of circulation of air, so that only the outer branches are capable of bringing fruit to maturity. "It is no uncommon sight (says he) to see trees in this district, with two or three tires of boughs pressing down hard upon one another, with their twigs so intimately interwoven, that even when the leaves are off, a small bird can scarcely creep in among them.

2. The mistletoe in this country is a great enemy to the apple-tree. It is easily pulled out with hooks in frosty weather, when, being brittle, it readily breaks off from the branches. It likewise may be applied to a profitable purpose, sheep being as fond of it as of ivy.

3. Moss can only be got the better of by industry in clearing the trees of it; and in Kent there are people who make it their profession to do so.

4. Spring-frosts, especially when they suddenly succeed rain, are great enemies to fruit-trees; dry frosts only keep back the blossoms for some time. Art can give no farther assistance in this case than to keep the trees in a healthy and vigorous state, so as to enable them to throw out a strength of bud and blossom; and by keeping them thin of wood, to give them an opportunity of drying quickly before the frost set in.

5. Blight is a term, as applied to fruit-trees, which Mr Marshall thinks is not understood. Two bearing years, he remarks, seldom come together; and he is of opinion, that it is the mere exhausting of the trees by the quantity of fruit which they have carried one year, that prevents them from bearing any the next. The only thing therefore that can be done in this case is, to keep the trees in as healthy and vigorous a state as possible.

6. Insects destroy not only the blossoms and leaves, but some of them also the fruit, especially pears. In the year 1783 much fruit was destroyed by wasps. Mr Marshall advises to set a price upon the female wasps in the spring; by which these mischievous insects would perhaps be exterminated, or at least greatly lessened.

7. An excess of fruit flints the growth of young trees, and renders all in general barren for two or three years; while in many cases the branches are broken off

off by the weight of the fruit; and in one case Mr Marshall mentions, that an entire tree had sunk under its burthen. To prevent as much as possible the bad effects of an excess of fruit, Mr Marshall recommends "to graft in the boughs," and when fully grown, to thin the bearing branches; thus endeavouring, like the gardener, to grow fruit every year."

157
Duration of
fruit-trees
may be
lengthened.

8. Though it is impossible to prevent the effects of old age, yet by proper management the natural life of fruit-trees may be considerably protracted. The most eligible method is to graft stocks of the native crab in the boughs. The decline of the tree is preceded by a gradual decline of fruitfulness, which long takes place before the tree manifests any sign of decay. During this decline of fruitfulness, there is a certain period when the produce of a tree will no longer pay for the ground it occupies, and beyond this period it ought by no means to be allowed to stand. In the Vale of Gloucester, however, our author saw an instance of some healthy bearing apple-trees, which then had the *second* tops to the same stems. The former tops having been worn out, were cut off, and the stumps saw-grafted. Our author observes, that the pear-tree is much longer lived than the apple, and ought never to be planted in the same ground. He concludes with the following general observation: "Thus considering fruit-trees as a crop in husbandry, the general management appears to be this: Plant upon a recently broken-up worn-out sward. Keep the soil under a state of arable management, until the trees be well grown: then lay it down to grass, and let it remain in sward until the trees be removed, and their roots be decayed; when it will again require a course of arable management."

ture of tim-
ber-trees.

SECT. VIII. *Of Timber-Trees.*

THE importance and value of these is so well known, that it is superfluous to say any thing on that subject at present: notwithstanding this acknowledged value, however, the growth of timber is so slow, and the returns for planting so distant, that it is generally supposed for a long time to be a positive loss, or at least to be attended with no profit. This matter, however, when properly considered, will appear in another light. There are four distinct species of woodlands; *viz.* woods, timber-groves, coppices, and woody wastes. The woods are a collection of timber-trees and underwood; the timber groves contain timber-trees without any underwood; and the coppices are collections of underwood alone. All these turn out to advantage sooner or later, according to the quick or slow growth of the trees, and the situation of the place with respect to certain local advantages. Thus in some places underwood is of great consequence, as for rails, hoops, stakes, fuel, &c. and by reason of the quickness of its growth it may be accounted the most profitable of all plantations. An osier-bed will yield a return of profit the second or third year, and a coppice in 15 or 20 years; while a plantation of oaks will not arrive at perfection in less than a century. This last period is so long, that it may not unreasonably be supposed likely to deter people from making such plantations of this kind, as few are willing to take any trouble for what they are never to see in perfection. It must be

159
Different
kinds of
woodlands.

160
What plan-
tations will
soonest
bring in a
return of
profit.

remembered, however, that though the trees themselves do not come to perfection in a shorter time, the value of the ground will always increase in proportion to their age. Thus, says one author upon this subject, "we have some knowledge of a gentleman now living, who during his lifetime has made plantations, which in all probability will be worth to his son as much as his whole estate, handsome as it is. Supposing that those plantations have been made 50 or 60 years, and that in the course of 20 or 30 more they will be worth L. 50,000; may we not say, that at present they are worth some 20,000 l. or 30,000 l? Mr Pavier, in the 4th volume of Bath Papers, computes the value of 50 acres of oak timber in 100 years to be L. 12,100, which is nearly 50s. annually per-acre; and if we consider that this is continually accumulating without any of that expence or risk to which annual crops are subject, it is probable that timber-planting may be accounted one of the most profitable articles in husbandry. Evelyn calculates the profit of 1000 acres of oak-land in 150 years, at no less than L. 670,000; but this is most probably an exaggeration. At any rate, however, it would be improper to occupy, especially with timber of such slow growth, the grounds which either in grass or corn can repay the trouble of cultivation with a good annual crop.

Timber-trees.

161
Advantages of
planting.

In the fourth volume of the Bath Papers, Mr Wagstaffe recommends planting as an auxiliary to cultivation. He brings an instance of the success of Sir William Jerringham, who made trial of "the most unpromising ground perhaps that any successful planter has hitherto attempted." His method was to plant beech trees at proper distances among Scotch firs, upon otherwise barren heaths. "These trees (says Mr Wagstaffe), in a soil perhaps without clay or loam, with the heathy sod trenched into its broken strata of sand or gravel, under the protection of the firs, have laid hold, though slowly, of the soil; and accelerated by the superior growth of the firs, have proportionally risen, until they wanted an enlargement of space for growth when the firs were cut down." He next proceeds to observe, that when the firs are felled, their roots decay in the ground; and thus furnish by that decay a new support to the soil on which the beeches grow: by which means the latter receive an additional vigour, as well as an enlargement of space and freer air; the firs themselves, though cut down before they arrived at their full growth, being also applicable to many valuable purposes.

162
Planting
meliorates
the soil.

In the 6th volume of Annals of Agriculture, we find the culture of trees recommended by Mr Harries: and he informs us, that the larch is the quickest grower and the most valuable of all the resinous timber-trees; but unless there be pretty good room allowed for the branches to stretch out on the lower part of the trunk, it will not arrive at any considerable size; and this observation, he says, holds good of all pyramidal trees. Scotch firs may be planted between them, and pulled out after they begin to obstruct the growth of the larch. Some of these larches he had seen planted about 30 years before, which at five feet distance from the ground measured from four feet to five feet six inches in circumference. The most barren grounds, he says, would answer for these trees, but better soil is required for the oaks. In this paper he takes notice

163
Culture of
timber-
trees re-
commended
by Mr
Harries.

Timber-trees.

164
Increase of
oak-trees.

tice of the leaves of one of his plantations of oaks having been almost entirely destroyed by insects; in consequence of which they did not increase in bulk as usual: but another which had nearly escaped these ravages, increased at an average one inch in circumference. "A tree four feet round (says he), that has timber 20 feet in length, gains by this growth a solid foot of timber annually, worth one shilling at least, and pays 5 *per cent.* for standing. It increases more as the tree gets from five to six feet round. I have a reasonable hope to infer from my inquiry, that I have in my groves 3000 oaks that pay me one shilling each per annum, or L.150 a year. My poplars have gained in circumference near two inches, and a Worcester and witch elm as much. I have lately been informed, that the smooth cut of a holly-tree, that measures 20 inches and upwards round, is worth to the cabinet-makers 2s. and 6d. per foot.

165
Increase of
trees in the
Marquis
of Lans-
downe's
plantation.

The following table shows the increase of trees in 21 years from their first planting. It was taken from the marquis of Lansdowne's plantation, begun in the year 1765, and the calculation made on the 15th of July 1786. It is about six acres in extent, the soil partly a swampy meadow upon a gravelly bottom. The measures were taken at five feet above the surface of the ground; the small firs having been occasionally drawn for posts and rails, as well as rafters for cottages; and when peeled of the bark, will stand well for seven years.

	Height in Feet.	Circumference in Feet. Inch.
Lombardy poplar -	60 to 80	4 8
Arbeal -	50 to 70	4 6
Plane -	50 to 60	3 6
Acacia -	50 to 60	2 4
Elm -	40 to 60	3 6
Chestnut -	30 to 50	2 9
Weymouth pines -	30 to 50	2 5
Cluster ditto -	30 to 50	2 5
Scotch fir -	30 to 50	2 10
Spruce ditto -	30 to 50	2 2
Larch -	50 to 60	3 10

From this table it appears, that planting of timber-trees, where the return can be waited for during the space of 20 years, will undoubtedly repay the original profits of planting, as well as the interest of the money laid out; which is the better worth the attention of a proprietor of land, that the ground on which they grow may be supposed good for very little else. From a comparative table of the growth of oak, ash, and elm timber, given in the 11th volume of the Annals of Agriculture, it appears that the oak is by much the slowest grower of the three.

166
Of under-
wood, &c.

With respect to the growth of under-wood, which in some cases is very valuable, it is to be remarked, that in order to have an annual fall of it, the whole quantity of ground, whatever its extent may be, ought to be divided into annual sowings. The exact number of sowings must be regulated by the uses to which it is intended to be put. Thus if, as in Surrey, stakes, edders, and hoops are saleable, there ought to be eight or ten annual sowings; or if, as in Kent, hop-poles are demanded, 14 or 15 will be required; and if, as in Yorkshire, rails be wanted, or, as in Gloucestershire, cordwood be most marketable, 18 or 20

sowings will be necessary to produce a succession of annual falls. Thus the business, by being divided, will be rendered less burthensome: a certain proportion being every year to be done, a regular set of hands will, in proper season, be employed; and by beginning upon a small scale, the errors of the first year will be corrected in the practice of the second, and those of the second in that of the third. The produce of the intervals will fall into regular course; and when the whole is completed, the falls will follow each other in regular succession. The greatest objection to this method of sowing woodlands is the extraordinary trouble in fencing: but this objection does not hold if the sowings lie at a distance from one another; on the contrary, if they lie together, or in plots, the entire plot may be inclosed at once; and if it contain a number of sowings, some subdivisions will be necessary, and the annual sowings of these subdivisions may be fenced off with hurdles, or some other temporary contrivance; but if the adjoining land be kept under the plough, little temporary fencing will be necessary. It must be observed, however, that in raising a woodland from seeds, it is not only necessary to defend the young plants against cattle and sheep, but against hares and rabbits also: so that a close fence of some kind is absolutely necessary. See the articles FENCE and HEDGE.

With regard to the preparation of the ground for raising timber, it may be observed, that if the soil be of a stiff clayey nature, it should receive a whole year's fallow as for wheat; if light, a crop of turnips may be taken; but at all events it must be made perfectly clean before the tree seeds be sown, particularly from perennial root weeds; as, after the seeds are sown, the opportunity of performing this necessary business is in a great measure lost. If the situation be moist, the soil should be gathered into wide lands, sufficiently round to let the water run off from the surface, but not high. The time of sowing is either the month of October or March; and the method as follows: "The land being in fine order, and the season favourable, the whole should be sown with corn or pulse adapted to the season of sowing: if in autumn, wheat or rye may be the crop; but if in spring, beans or oats. Whichever of these three species be adopted, the quantity of seed ought to be less than usual, in order to give a free admission of air, and prevent the crop from lodging. The sowing of the grain being completed, that of the tree-seeds must be immediately set about. These are to be put in drills across the land: acorns and nuts should be dibbled in, but keys and berries scattered in trenches or drills drawn with the corner of a hoe, in the manner that gardeners sow their pease. The distance might be a quarter of a statute rod, or four feet and one inch and an half. A land chain should be used in setting out the drills, as not being liable to be lengthened or shortened by the weather. It is readily divided into rods; and the quarters may be easily marked.

The species of under-wood to be sown must be determined by the consumpt of it in the neighbourhood of the plantation. Thus, if stakes, hoops, &c. be in request, the oak, hazel, and ash, are esteemed as under-wood. Where charcoal is wanted for iron forges, beech is the prevailing underwood. The oak, box,

167
Method of
sowing.

Timber-trees.

box, birch, &c. are all in request in different countries, and the choice must be determined by the prevailing demand. As the keys of the ash sometimes lie two or even three years in the ground, it will be proper to have the places where they are sown distinguished by some particular marks, to prevent them from being disturbed by the plough after harvest; as a few beans scattered along with them, if the crop be oats; or oats, if the crop be beans. The crop should be *reaped*, not *mown*, at harvest time, and be carried off as fast as possible. Between harvest and winter, a pair of furrows should be laid back to back in the middle of each interval, for meliorating the next year's crop, and laying the seedling plants dry; while the stubble of the unploughed ground on each side of the drills will keep them warm during the winter. The next year's crop may be potatoes, cabbages, turnips, or if the first was corn, this may be beans; if the first was beans, this may be wheat drilled. In the spring of the third year the drills which rose the first year must be looked over, and the vacancies filled up from those parts which are thickest; but the drills of the ash should be let alone till the fourth year. The whole should afterwards be looked over from time to time; and this, with cultivating the intervals, and keeping the drills free from weeds, will be all that is necessary until the tops of the plants begin to interfere.

The crops may be continued for several years; and if they only pay for the expences, they will still be of considerable advantage by keeping the ground stirred, and preserving the plants from hares and rabbits. Even after the crops are discontinued, the ground ought still to be stirred, alternately throwing the

mould to the roots of the plants, and gathering it into a ridge in the middle of the interval. The best method of doing this is to split the ground at the approach of winter in order to throw it up to the trees on both sides; this will preserve the roots from frost: gather it again in the spring, which will check the weeds, and give a fresh supply of air: split again at mid-summer, to preserve the plants from drought: gather, if necessary, in autumn, and split as before at the approach of winter. The spring and mid-summer ploughings should be continued as long as a plough can pass between the plants.

Whenever the oaks intended for timber are in danger of being drawn up too slender for their height, it will be necessary to cut off all the rest at the height of about an handbreadth above the ground; and those designed to stand must now be planted at about two rods distant from each other, and as nearly a quincunx as possible. The second cutting must be determined by the demand there is for the underwood; with only this proviso, that the timber stands be not too much crowded by it; for rather than this should be the case, the coppice should be cut, though the wood may not have reached its most profitable state. What is here said of the method of rearing oak-trees in woods, is in a great measure applicable to that of raising other trees in timber-groves. The species most usually raised in these are the ash, elm, beech, larch, spruce fir, Weymouth pine, poplar, willow, alder, chestnut, walnut, and cherry. The three last are used as substitutes for the oak and beech, and these two for the mahogany.

Timber-trees.

PART III. Of the CATTLE proper to be employed in FARM-WORK; REARING and MANAGEMENT of them. Of HOGS, POULTRY, &c. MANAGEMENT of BEES. Of the DAIRY. Of MANURES.

SECT. I. Of the Cattle proper to be employed.

As great part of the stock of an husbandman must always consist of cattle, and one of his principal expences in the maintenance of them, this part of his business is certainly to be looked upon as one of the most important of the whole. The cattle belonging to a farm may be divided into two classes, viz. such as are intended for work, and such as are designed for sale. The former are now principally horses, the oxen formerly employed being fallen into disuse, though it does not yet certainly appear that the reasons for the exchange are satisfactory. In the second volume of Bath Papers, we have account of a comparative experiment of the utility of horses and oxen in husbandry by Mr Kedington near Bury in Suffolk, in which the preference is decisively given to oxen. He informs us, that at the time he began the experiment (in 1779), he was almost certain that there was not an ox worked in the whole county; finding, however, the expence of horses very great, he purchased a single pair of oxen, but found much difficulty in breaking them, as the workmen were so much prejudiced against them, that they would not take the proper pains. At last he met with a labourer who undertook the task; and the

oxen "soon became as tractable and as handy, both at ploughing and carting, as any horses." On this he determined to part with all his cart-horses; and by the time he wrote his letter, which was in 1781, he had not a single horse, nor any more than six oxen; which inconsiderable number performed with ease all the work of his farm (consisting of upwards of 100 acres of arable land and 60 of pasture and wood), besides the statute duty on the highways, timber and corn, carting, harrowing, rolling, and every part of rural business. They are constantly shod; their harness is the same as that of horses (excepting the necessary alterations for difference of size and shape); they are driven with bridles and bits in their mouths, answering to the same words of the ploughman and carter as horses will do. A single man holds the plough, and drives a pair of oxen with reins: and our author informs us, that they will plough an acre of ground in less than eight hours time; he is of opinion that they would do it in seven. The intervals of a small plantation, in which the trees are set in rows ten feet asunder, are ploughed by a single ox with a light plough, and he is driven by the man who holds it. The oxen go in a cart either single, or one, two, or three, according to the load. Four oxen will draw 80 bushels of barley or oats in a waggon with ease; and if good

Cattle to be employed.

169
Reasons for preferring oxen to horses.

of their kind, will travel as fast as horses with the same load. One ox will draw 40 bushels in a light cart, which our author thinks is the best carriage of any. On the whole, he prefers oxen to horses for the following reasons.

1. They are kept at much less expence, never eating meal or corn of any kind. In winter they are fed with straw, turnips, carrots, or cabbages; or instead of the three last, they have each a peck of bran per day while kept constantly at work. In the spring they eat hay; and if working harder than usual in feed-time, they have bran besides. When the vetches are fit for mowing, they get them only in the stable. After the day's work in summer they have a small bundle of hay, and stand in the stable till they cool; after which they are turned into the pasture. Our author is of opinion, that an ox may be maintained in condition, for the same constant work as an horse, for at least 4l. less annually.

2. After a horse is seven years old, his value declines every year; and when lame, blind, or very old, he is scarce worth any thing; but an ox, in any of these situations, may be fatted, and sold for even more than the first purchase; and will always be fat sooner after work than before.

3. Oxen are less liable to diseases than horses.

4. Horses are frequently liable to be spoiled by servants riding them without their master's knowledge, which is not the case with oxen.

5. A general use of oxen would make beef plentiful, and consequently all other meat; which would be a national benefit.

170
Difficulty in shoeing oxen.

Mr Kedington concludes his paper with acknowledging, that there is one inconvenience attending the use of oxen, viz. that it is difficult to shoe them; tho' even this, he thinks, is owing rather to the unskilfulness of the smiths who have not been accustomed to shoe these animals, than to any real difficulty. He confines them in a pound while the operation is performing.

171
Mr Marshall's calculations.

Mr Marshall, in his Rural Economy of the Midland counties, shows the advantage of employing oxen in preference to horses from the mere article of expence, which, according to his calculation, is enormous on the part of the horses. He begins with estimating the number of square miles contained in the kingdom of England; and this he supposes to be 30,000 of cultivated ground. Supposing the work of husbandry to be done by horses only, and each square mile to employ 20 horses, which is about 3 to 100 acres, the whole number used throughout Britain would be 600,000; from which deducting one sixth for the number of oxen employed at present, the number of horses just now employed will be 500,000. Admitting that each horse works ten years, the number of farm-horses which die annually are no fewer than 50,000; each of which requires full four years keep before he is fit for work. Horses indeed are broke in at three, some at two, years old, but they are, or ought to be, indulged in keep and work till they are six; so that the cost of rearing and keeping may be laid at full four ordinary years. For all this consumption of vegetable produce he returns not the community a single article of food, clothing, or commerce; even his skin for economical purposes being barely worth the taking off. By working horses in the affairs of husbandry, therefore, "the community is losing annually the amount

of 200,000 years keep of a growing horse;" which at the low estimate of five pounds a-year, amounts to a million annually. On the contrary, supposing the business of husbandry to be done solely by cattle, and admitting that oxen may be fatted with the same expediture of vegetable produce as that which old horses require to fit them for full work, and that instead of 50,000 horses dying, 50,000 oxen, of no more than 52 stone each, are annually slaughtered; it is evident, that a quantity of beef nearly equal to what the city of London consumes would be annually brought into the market; or, in other words, 100,000 additional inhabitants might be supplied with one pound of animal food a-day each; and this without consuming one additional blade of grass. "I am far from expecting (says Mr Marshall), that cattle will, in a short space of time, become the universal beasts of draft in husbandry; nor will I contend, that under the present circumstances of the island they ought in strict propriety to be used. But I know that cattle, under proper management, and kept to a proper age, are equal to every work of husbandry, in most if not all situations: And I am certain, that a much greater proportion than there is at present might be worked with considerable advantage, not to the community only, but to the owners and occupiers of lands. If only one of the 50,000 carcases now lost annually to the community could be reclaimed, the saving would be an object."

In Norfolk, our author informs us that horses are the only beasts of labour; and that there is not perhaps one ox worked throughout the whole county. It is the same in the Vale of Gloucester, though oxen are used in the adjoining counties. Formerly some oxen were worked in it double; but they were found to poach the land too much, and were therefore given up. Even when worked single, the same objection is made: but, says Mr Marshall, "in this I suspect there is a spice of obstinacy in the old way; a want of a due portion of the spirit of improvement; a kind of indolence. It might not perhaps be too severe to say of the Vale farmers, that they would rather be eaten up by their horses than step out of the beaten tract to avoid them." Shoeing oxen with whole shoes, in our author's opinion, might remedy the evil complained of; but "if not, let those (says he) who are advocates for oxen calculate the comparative difference in wear and keep, and those who are their enemies estimate the comparative mischiefs of trading; and thus decide upon their value as beasts of labour in the Vale."

In the Cotswold oxen are worked as well as horses; but the latter, our author fears, are still in the proportion of two to one: he has the satisfaction to find, however, that the former are coming into more general use. They are worked in harness; the collar and harness being used as for horses, not reversed, as in most cases they are for oxen. "They appear (says our author) to be perfectly handy, and work, either at plough or cart, in a manner which shows, that although horses may be in some cases convenient, and in most cases pleasurable to the driver, they are by no means necessary to husbandry. A convenience used in this country is a moveable harness-house, with a sledge bottom, which is drawn from place to place as occasion may require. Thus no labour is lost either by the oxen or their drivers."

177
Why the use of oxen is declining in Yorkshire.

178
Superiority of oxen to horses.

In Yorkshire oxen are still used, though in much fewer numbers than formerly; but our author does not imagine this to be any decisive argument against their utility. The Yorkshire plough was formerly of such an unwieldy construction, that four or six oxen, in yokes, led by two horses, were absolutely requisite to draw it; but the improvements in the construction of the plough have of late been so great, that two horses are found to be sufficient for the purpose; so that as Yorkshire has all along been famous for its breed of horses, we are not to wonder at the present disuse of oxen. Even in carriages they are now much disused; but Mr Marshall assigns as a reason for this, that the roads were formerly deep in winter, and soft to the hoof in summer; but now they are universally a causeway of hard limestones, which hurt the feet of oxen even when shod. Thus it even appears matter of surprise to our author that so many oxen are employed in this county; and the employment of them at all is to him a convincing argument of their utility as beasts of draught. The timber carriers still continue to use them, even though their employment be solely upon the road. They find them not only able to stand working every day provided their feet do not fail them, but to bear long hours better than horses going in the same pasture. An ox in a good pasture soon fills his belly, and lies down to rest; but an horse can scarce satisfy his hunger in a short summer's night. Oxen are also considered as much superior at a difficult pull to horses; but this he is willing to suppose arises from their using half-bred hunters in Yorkshire, and not the true breed of cart horses. "But what (says he) are thorough-bred cart-horses? Why, a species of strong, heavy, sluggish animals, adapted solely to the purpose of draught; and according to the present law of the country, cannot, without an annual expence, which nobody bestows upon them, be used for any other purpose. This species of beasts of draught cost at four years old from 20l. to 30l.; they will, with extravagant keep, extraordinary care and attendance, and much good luck, continue to labour eight or ten years; and may then generally be sold for five shillings a-head. If we had no other species of animals adapted to the purposes of draught in the island, cart-horses would be very valuable, they being much superior to the breed of saddle-horses for the purpose of draught. But it appears evident, that were only a small share of the attention paid to the breeding of draught oxen which is now bestowed on the breeding of cart-horses; animals equally powerful, more active, less costly, equally adapted to the purposes of husbandry if harnessed with equal judgment, less expensive in keep and attendance, much more durable, and infinitely more valuable after they have finished their labours, might be produced. A steer, like a colt, ought to be familiarized to harness at two or three years old, but should never be subjected to hard labour until he be five years old; from which age, until he be 15 or perhaps 20, he may be considered as in his prime as a beast of draught. An ox which I worked several years in Surrey, might at 17 or 18 years of age have challenged for strength, agility, and sagacity, the best bred cart-horse in the kingdom."

SECT. II. Of different Kinds of Horses, and the Methods of Breeding, Rearing, and Feeding them.

Different kinds of horses.

THE midland counties of England have for some time been celebrated on account of their breed of the *black cart-horse*; though Mr Marshall is of opinion that this kind are unprofitable as beasts of draught in husbandry. The present improvement in the breed took its rise from six Zealand mares sent over by the late Lord Chesterfield during his embassy at the Hague. These mares being lodged at his lordship's seat at Bretby in Derbyshire, the breed of horses thus became improved in that county, and for some time it took the lead for the species of these animals. As the improved breed passed into Leicestershire, however, through some unknown circumstances, it became still more improved, and Leicester has for some time taken the lead. It is now found, however, that the very large horses formerly bred in this district are much less useful than such as are of a smaller size. Mr Marshall describes in magnificent terms one of these large horses, a stallion belonging to Mr Bakewell named K (A), which, he says, was the handsomest horse he ever saw. "He was (says he) the fancied *war-horse* of the German painters; who, in the luxuriance of imagination, never perhaps excelled the natural grandeur of this horse. A man of moderate size seemed to shrink behind his fore-end, which rose so perfectly upright, his ears stood (as Mr Bakewell says every horse's ears ought to stand) perpendicularly over his fore feet. It may be said, with little latitude, that in grandeur and symmetry of form, viewed as a picturable object, he exceeded as far the horse which this superior breeder had the honour of showing to his Majesty, and which was afterwards shown publicly at London, as that horse does the meanest of the breed." A more *useful* horse, bred also by Mr Bakewell, however, is described as having "a thick carcase, his back short and straight, and his legs short and clean: as strong as an ox, yet active as a poney; equally suitable for a cart or a lighter carriage."

179
Account of the black cart-horse.

The stallions in this county are bred either by farmers or by persons whose business it is to *breed* them, and who therefore have the name of *breeders*. These last either cover with them themselves, or let them out to others for the season, or sell them altogether to stallion-men who travel about with them to different places.—The prices given for them are from 50 to 200 guineas by purchase; from 40 to 80 or a hundred by the season; or from half a guinea to two guineas by the mare. The mares are mostly kept by the farmers, and are worked until near the times of foaling, and moderately afterwards while they suckle: the best time for foaling is supposed to be the month of March or April; and the time of weaning that of November.—"The price of foals (says Mr Marshall), for the last ten years, has been from five to ten pounds or guineas; for yearlings, 10 to 15 or 20; for two-year-olds, 15 to 25 or 30; for six-year-olds, from 25 to 40 guineas."—Our author acknowledges that this breed of horses, considered abstractedly in the light in which they appear here, are evidently a profitable species of live stock, and as far as there is a market for six-years-old horses of this breed, it is profitable to agriculture.

180

gricuture. "But (says he) viewing the business of agriculture in general, not one occupier in ten can partake of the profit; and being kept in agriculture after they have reached that profitable age, they become indisputably one of its heaviest burdens. For besides a cessation of improvement of four or five guineas a year, a decline in value of as much yearly takes place. Even the brood-mares, after they have passed that age, may, unless they be of a very superior quality, be deemed unprofitable to the farmer."

183
Norfolk
breed de-
scribed.

Our author complains that the ancient breed of Norfolk horses is almost entirely worn out. They were small, brown-muzzled, and light-boned; but they could endure very heavy work with little food: two of them were found quite equal to the plough in the soil of that county, which is not deep. The present breed is produced by a cross with the large one of Lincolnshire and Leicestershire already mentioned. He approves of the Suffolk breed, which (he says) are a "half-horse half-hog race of animals, but better adapted to the Norfolk husbandry than the Leicestershire breed; their principal fault, in his opinion, is a flatness of the rib.—In the Vale of Gloucester most farmers rear their own plough-horses, breeding of horses not being practised. They are of a very useful kind, the colour mostly black, inclinable to tan colour, short and thick in the barrel, and low on their legs. The price of a six-year-old horse from 25l. to 35l. Some cart horses are bred in Cotswold hills; the mares are worked till the time of foaling, but not while they suckle; and the foals are weaned early, while there is plenty of grain upon the ground.

185
Yorkshire
horses.

Yorkshire, which has been long celebrated for its breed of horses, still stands foremost in that respect among the English counties. It is principally remarkable for the breed of saddle-horses, which cannot be reared in Norfolk, though many attempts have been made for that purpose. Yorkshire stallions are frequently sent into Norfolk; but though the foals may be handsome when young, they lose their beauty when old. In Yorkshire, on the other hand, though the foal be ever so unpromising, it acquires beauty, strength, and activity as it grows up. Mr Marshall supposes that from five to ten thousand horses are annually bred up between the eastern Morelands and the Humber.

"Thirty years ago (says Mr Marshall), strong saddle-horses, fit for the road only, were bred in the Vale; but now the prevailing breed is the fashionable coach-horse, or a tall, strong, and over-sized hunter; and the shows of stallions in 1787 were flat and spiritless in comparison with those of 1783." The black cart-horse, an object of Mr Marshall's peculiar aversion, is also coming into the Vale.

In the breeding of horses he complains greatly of the negligence of the Yorkshire people, the mares being almost totally neglected; though in the brute creation almost every thing depends upon the female.

With regard to the general maintenance of horses, we have already mentioned in this article, and that of AGRICULTURE, several kinds of food upon which experiments have been made with a view to determine the most profitable mode of keeping them. Perhaps, however, the most certain method of ascertaining this matter is by observing the practice of those counties where horses are most in use. Mr Marshall recommends

the Norfolk management of horses as the cheapest method of feeding them practised any where; which, however, he seems willing to ascribe in a great measure to the excellency of their breed. In the winter months, when little work is to be done, their only rack-meat is barley-straw; a reserve of clover-hay being usually made against the hurry of seed-time. A bushel of corn in the most busy season is computed to be an ample allowance for each horse, and in more leisure times a much less quantity suffices. Oats and sometimes barley, when the latter is cheap and unsaleable, are given; but in this case the barley is generally malted, *i. e.* steeped and afterwards spread abroad for a few days, until it begin to vegetate, at which time it is given to the horses, when it is supposed to be less heating than in its natural state. Chaff is universally mixed with horse-corn: the great quantities of corn grown in this country afford in general a sufficiency of *natural* chaff; so that *cut chaff* is not much in use: the chaff, or rather the awns of barley, which in some places are thrown as useless to the dunghil, are here in good esteem as provender. Oat-chaff is deservedly considered as being of much inferior quality.—It may here be remarked, that this method of keeping horses which Mr Marshall approves of in the Norfolk farmers, is practised, and probably has been so from time immemorial, in many places of the north of Scotland; and is found abundantly sufficient to enable them to go through the labour required. In summer they are in Norfolk kept out all night, generally in clover leys, and in summer their keep is generally clover only, a few tares excepted.

In the fourth volume of the Annals of Agriculture, Mr Young gives an account of the expence of keeping horses; which, notwithstanding the vast numbers kept in the island, seems still to be very indeterminate, as the informations he received varied no less than from L. 8 to L. 25 a-year. From accounts kept on his own farm of the expence of horses kept for no other purpose than that of agriculture, he stated them as follows:

	£.	s.	d.
1763 Six horses cost per horse	10	13	0
1764 Seven do.	8	10	11
1765 Eight do.	14	6	6
1766 Six do.	12	18	9

Average on the whole L. 11 : 12 : 3.

By accounts received from *Northmins* in Herefordshire, the expences stood as follows:

	£.	s.	d.
1768 Expence per horse	20	7	0
1769	15	8	5
1770	14	14	2
1771	15	13	3
1772	18	4	0
1773	15	11	8
1774	14	4	5
1775	19	0	5
1776	16	14	5

Average L. 16 : 13 : 1.

On these discordant accounts Mr Young observes, undoubtedly with justice, that many of the extra expences depend on the extravagance of the servants; while some of the apparent savings depend either on their carelessness, or *stealing* provender to their beasts privately,

privately, which will frequently be done. He concludes, however, as follows: "The more exactly the expence of horses is examined into, the more advantageous will the use of oxen be found. Every day's experience convinces me more and more of this. If horses kept for use alone, and not for show, have proved thus expensive to me, what must be the expence to those farmers who make their fat sleek teams an object of vanity? It is easier conceived than calculated.

SECT. III. *Of the Breeding and Rearing of Black Cattle.*

THESE are reared for the two different purposes, viz. work, and fattening for slaughter. For the former purpose, Mr Marshall remarks, that it is obviously necessary to procure a breed without horns. This he thinks would be no disadvantage, as *horn*, though formerly an article of some request, is now of very little value. The horns are quite useless to cattle in their domestic state, though nature has bestowed them upon them as weapons of defence in their wild state; and our author is of opinion that it would be quite practicable to produce a hornless breed of black-cattle as well as of sheep, which last has been done by attention and perseverance; and there are now many hornless breeds of these creatures in Britain. Nay, he insists, that there are already three or four breeds of hornless cattle in the island; or that there are many kinds of which numbers of individuals are hornless, and from these by proper care and attention a breed might be formed. The first step is to select females; and having observed their imperfections, to endeavour to correct them by a well chosen male.

189
A hornless

sirable for
work.

190
Properties
requisite in
black cat-
tle.

The other properties of a perfect breed of black cattle for the purposes of the dairy as well as others, ought, according to Mr Marshall, to be as follows. 1. The head small and clean, to lessen the quantity of offal. 2. The neck thin and clean, to lighten the fore-end, as well as to lessen the collar, and make it sit close and easy to the animal in work. 3. The carcass large, the chest deep, and the bosom broad, with the ribs standing out full from the spine; to give strength of frame and constitution, and to admit of the intestines being lodged within the ribs. 4. The shoulders should be light of bone, and rounded off at the lower point, that the collar may be easy, but broad to give strength; and well covered with flesh for the greater ease of draught, as well as to furnish a desired point in fattening cattle. 5. The back ought to be wide and level throughout; the quarters long; the thighs thin, and standing narrow at the round bone; the udder large when full, but thin and loose when empty, to hold the greater quantity of milk; with large dug-veins to fill it, and long elastic teats for drawing it off with greater ease. 6. The legs (below the knee and hock) straight, and of a middle length; their bone, in general, light and clean from fleshiness, but with the joints and sinews of a moderate size, for the purposes of strength and activity. 7. The flesh ought to be mellow in the state of fleshiness, and, firm in the state of fatness. 8. The hide mellow, and of a middle thickness, though in our author's opinion this is a point not yet well determined.

As the milk of cows is always an article of great importance, it becomes an object to the husbandman, if possible, to prevent the waste of that useful fluid, which in the common way of rearing calves is unavoidable. A method of bringing up these young animals at less expence is proposed by the Duke of Northumberland. His plan is to make skimmed milk answer the purpose of that which is newly drawn from the teat; and which, he supposes, might answer the purpose at one third of the expence of new milk. The articles to be

added to the skimmed milk are treacle and the common linseed oil cake ground very fine, and almost to an impalpable powder, the quantities of each being so small, that to make 32 gallons would cost only 6 d. besides the skimmed milk. It mixes very readily and almost intimately with the milk, making it more rich and mucilaginous, without giving it any disagreeable taste. The receipt for making it is as follows. Take one gallon of skimmed milk, and to about a pint of it add half an ounce of treacle, stirring it until it is well mixed; then take one ounce of linseed oil-cake finely pulverised, and with the hand let it fall gradually in very small quantities into the milk, stirring it in the mean time with a spoon or ladle until it be thoroughly incorporated; then let the mixture be put into the other part of the milk, and the whole be made nearly as warm as new milk when it is first taken from the cow, and in that state it is fit for use. The quantity of the oil cake powder may be increased from time to time as occasion requires, and as the calf becomes inured to its flavour. On this subject Mr Young remarks, that in rearing calves, there are two objects of great importance. 1. To bring them up without any milk at all; and, 2. To make skimmed milk answer the purpose of such as is newly milked or sucked from the cow. In consequence of premiums offered by the London Society, many attempts have been made to accomplish these desirable purposes; and Mr Budel of Wanborough in Surrey was rewarded for an account of his method. This was no other than to give the creatures a gruel made of ground barley and oats. Mr Young, however, who tried this method with two calves, assures us that both of them died, though he afterwards put them upon milk when they were found not to thrive. When in Ireland he had an opportunity of purchasing calves at three days old from 20d. to 3s. each; by which he was induced to repeat the experiment many times over. This he did in different ways, having collected various receipts. In consequence of these he tried hay-tea, bean-meal mixed with wheat-flour, barley and oats ground nearly, but not exactly, in Mr Budd's method; but the principal one was flax-seed boiled into a jelly, and mixed with warm water; this being recommended more than all the rest. The result of all these trials was, that out of 30 calves only three or four were reared; these few were brought up with barley and oatmeal, and a very small quantity of flax-seed jelly; one only excepted, which at the desire of his coachman was brought up on a mixture of two-thirds of skimmed milk and one third of water, with a small addition of flax-jelly well dissolved.

The second object, viz. that of improving skimmed milk, according to the plan of the Duke of Northumberland, seems to be the more practicable of the two.

cattle.

Mr Young informs us, that it has answered well with him for two seasons; and two farmers to whom he communicated it gave likewise a favourable report.

193
Method of
rearing
calves in
Cornwall.

In the third volume of the same work, we are informed that the Cornwall farmers use the following method in rearing their calves. "They are taken from the cow from the fourth to the sixth day; after which they have raw milk from six to ten or 14 days. After this they feed them with scalded skimmed milk and gruel made of shelled oats, from three quarts to four being given in the morning, and the same in the evening. The common family broth is thought to be as good or better than the gruel, the favour of the salt being supposed to strengthen their bowels. The proportion of gruel or broth is about one third of the milk given them. A little fine hay is set before them, which they soon begin to eat.

194
Mr Crook's
method.

In the fifth volume of Bath Papers, we have an account by Mr Crook of a remarkably successful experiment on rearing calves without any milk at all. This gentleman, in 1787, weaned 17 calves; in 1788, 23; and in 1789, 15. In 1787, he bought three sacks of linseed, value L. 2, 5s. which lasted the whole three years. One quart of it was put to six quarts of water; which, by boiling 10 minutes, was reduced to a jelly: the calves were fed with this mixed with a small quantity of tea, made by steeping the best hay in boiling water. By the use of this food three times a day, he says that his calves throve better than those of his neighbours which were reared with milk.—These unnatural kinds of food, however, are in many cases apt to produce a looseness, which in the end proves fatal to the calves. In Cornwall they remedy this sometimes by giving acorns as an astringent; sometimes by a cordial used for the human species, of which opium is the basis.

195
Norfolk
method,
&c.

In Norfolk, the calves are reared with milk and turnips; sometimes with oats and bran mixed among the latter. Winter calves are allowed more milk than summer-ones; but they are universally allowed new milk, or even to suck.—In the midland counties bull-calves are allowed to remain at the teat until they be six, nine, or twelve months old, letting them run either with their dams or with cows of less value bought on purpose. Each cow is generally allowed one male or two female calves. Thus they grow very fast, and become surprisingly vigorous. The method of the dairy-men is to let the calves suck for a week or a fortnight according to their strength; next they have new milk in pails for a few meals; after that new and skimmed milk mixed; then skimmed milk alone, or porridge made with milk, water, ground oats, &c. sometimes with oil-cake, &c. until cheese-making commences; after which they have whey-porridge, or sweet whey in the field, being carefully housed in the night until the warm weather come in.

196
Of fatten-
ing cattle.

With regard to the method of fattening cattle, turnips are coming into general use throughout Britain. In Norfolk no other method is thought of. The general rule is, to allow them to eat their turnips in the field while the weather remains moderately warm, but to give them under cover when it becomes wet or very cold. In this respect, however, there is a considerable difference with regard to the manner in which the cattle have been brought up; for such as have been accus-

N^o 160.

tomed to a severe climate will stand the winter in the field much better than those which have been brought up under shelter. It is likewise asserted by some, with a great deal of probability, that the flesh of cattle fattened under cover is less agreeable than that of such as are allowed to remain in the open air.

Rearing
and fatten-
ing hogs.

SECT. IV. *Of the Rearing and Fattening of Hogs.*

THE practice of keeping these animals is so general, especially in England, that one should think the profit attending it would be absolutely indisputable; and this the more especially when it is considered how little nicety they have in their choice of food. From such experiments, however, as have been made, the matter appears to be at least very doubtful, unless in particular circumstances. In the first volume of Annals of Agriculture, we have an experiment by Mr Mure of feeding hogs with the cluster-potato and carrots; by which it appeared, that the profit on large hogs was much greater than on small ones; the latter eating almost as much as the former, without yielding a proportionable increase of flesh. The gain was counted by weighing the large and small ones alive; and it was found, that from November 10th to January 5th, they had gained in the following proportion:

20 large hogs,	-	-	-	L. 1	3	6
20 small,	-	-	-	0	7	8
2 stag hogs,	-	-	-	1	17	8

On being finished with pease, however, it appeared, that there was not any real profit at last; for the accounts stood ultimately as follow:

Dr.				Cr.			
Value of hogs at putting up,				42 hogs sold fat at			
33 coomb pease, at 14s.	-	23	2	0	L. 95	0	0
2 do. 2 bushels barley, at 14s.	-	1	15	0			
56 days attendance of one man, at 14d.	-	3	5	4			
950 bushels of carrots, and 598 of potatoes, at 3½d. per bushel,	-	22	15	8			
					L. 95	0	0
					L. 95	0	0

In some experiments by Mr Young, related in the same volume, he succeeded still worse, not being able to clear his expences. His first experiment was attended with a loss of one guinea per hog; the second, with a loss of 11s. 8d.; the third, of only 3s. In these three the hogs were fed with pease; given whole in the two first, but ground into meal in the last. The fourth experiment, in which the hog was fed with Jerusalem artichokes, was attended with no loss; but another, in which pease were again tried, was attended with a loss of 4s. Other experiments were tried with pease, which turning out likewise unfavourable, barley was tried ground along with pease and beans. This was attended with a small profit, counting nothing for the trouble of feeding the animals. The expences on two hogs were L. 14 : 13 : 10½, the value L. 15,

Sheep, &c. 11s. 3^d. so that there was a balance in his favour of 17s. 4^d. In another experiment, in which the hogs were fed with pease and barley ground, the beans being omitted as useless, there was a profit of 12s. 3d. upon an expence of L. 20 : 15 : 9 ; which our author supposes would pay the attendance. In this experiment the pease and barley meal were mixed into a liquid like cream, and allowed to remain in that state for three weeks, till it became sour. This was attended in two other instances with profit, and in a third with loss : however, Mr Young is of opinion, that the practice will still be found advantageous on account of the quantity of dung raised ; and that the farmer can thus use his pease and barley at home without carrying them to market.

198
Mr Marshall's remarks.

Mr Marshall remarks, that in the Midland district, oats are preferred to barley as a food both for young pigs and breeding sows. It is also supposed that young pigs require warm meat to make them grow quickly. Barley meal and potatoes are used in fattening them ; beans and pease being generally disused.—In this district it is common to keep two or three pigs in the sty along with the old hogs to be fatted. This is done that there may be no waste ; as the young pigs lick out the trough clean when the old ones are served. Mr Marshall observes, that in a confined place the old ones are apt to "lord it too much over the little ones ;" for which reason he would have a separate apartment assigned to them, with a door so small that the large swine should not be able to get into it.

SECT. V. *Sheep.*

SEE the article PASTURAGE.

SECT. VI. *Rabbits.*

In particular situations these animals may be kept to advantage, as they multiply exceedingly, and require no trouble in bringing up. A considerable number of them are kept in Norfolk, where many parts, consisting of barren hills or heaths, are proper for their reception. They delight in the sides of sandy hills, which are generally unproductive when tilled ; but level ground is improper for them. Mr Marshall is of opinion, that there are few sandy or other loose-soiled hills which would not pay better in rabbit warrens than any thing else. "The hide of a bullock (says he) is not worth more than $\frac{1}{10}$ th of his carcase ; the skin of a sheep may, in full wool, be worth from a sixth to a tenth of its carcase ; but the fur of a rabbit is worth twice the whole value of the carcase ; therefore supposing a rabbit to consume a quantity of food in proportion to its carcase, it is, on the principle offered, a species of stock nearly three times as valuable as either cattle or sheep. Rabbit warrens ought to be inclosed with a stone or sod wall ; and at their first stocking, it will be necessary to form burrows to them until they have time to make them to themselves. Boring the ground horizontally with a large augre is perhaps the best method that can be practised. Eagles, kites, and other birds of prey, as well as cats, weasels, and pole-cats, are great enemies of rabbits. The Norfolk warreners catch the birds by traps placed on the tops of stumps of trees or artificial hillocks of a con-

199
Rabbits more valuable than black cattle or sheep.

200
Method of destroying birds of prey.

VOL. VIII. Part II.

cal form, on which they naturally alight.—Traps also seem to be the only method of getting rid of the other enemies ; though thus the rabbits themselves are in danger of being caught.

SECT. VII. *Poultry.*

THOUGH these make a part of every husbandman's stock, the keeping of great numbers of them will never be found attended with any advantage ; as it is certain they never will pay for the grain necessary to sustain them, if that grain must be bought. On a farm, therefore, they are only useful to pick up what would otherwise be wasted ; and even thus we can only count them profitable at certain times of the year ; and their number must always be regulated by the size of the farm.—In Norfolk a great number of turkies are bred, of a size and quality superior to those in other parts. Mr Marshall accounts for their number in the following manner : "It is understood in general, that to rear turkies with success, it is necessary that a male bird should be kept upon the spot to impregnate the eggs singly ; but the good housewives of this country know, that a daily intercourse is unnecessary ; and that if the hen be sent to a neighbouring cock previous to the season of exclusion, one act of impregnation is sufficient for one brood. Thus relieved from the expence and disagreeableness of keeping a male bird, most little farmers, and many cottagers, rear turkies. This accounts for their number ; and the species and the food they are fatted with (which, I believe, is wholly buck) account for their superior size and quality."

201
Great number of turkies reared in Norfolk.

In some situations, particularly in the neighbourhood of great towns, it might perhaps be an object to rear considerable numbers of poultry, even though some part of the farm should be cultivated merely for their subsistence. It must, however, be remembered, that poultry cannot bear confinement. They are spoiled, not only by being kept in a house, but even in a yard and its environs ; for which reason Mr Young informs us, that Lord Clarendon constantly shifts his poultry through different parts of the park in which they are kept. In Norfolk it is customary to put young goslings upon green wheat.

202
Poultry will not thrive when confined.

SECT. VIII. *Bees.*

THESE may be considered as of considerable importance in husbandry, on account of the unlimited demand there is for honey and wax, and the little expence at which it is obtained. It is not, however, to be expected, that in all situations the honey produced will either be in equal quantity or of equal quality. This depends on the quantity and quality of the flowers in the neighbourhood to which the bees have access. Thus the honey of Norfolk is of inferior quality to that produced in other parts ; owing, as some have supposed, to the bees feeding upon the flowers of buck-wheat, which grows in great quantity throughout the county. Mr Marshall, however, ascribes its peculiar taste to the heaths and moorish places in Norfolk, to which the bees resort, and which seems to be a natural product of the Norfolk soil. He does not however assert, that the buck can have no effect upon it : he owns that the buck-flowers are luscious and disagreeable to many people ;

203
Difference of the quantity and quality of honey.

Bees, &c.

people, though those of beans are equally so to others; but wishes that their imparting any bad quality to honey may be doubted, until positive proof be brought to the contrary.

The Morelands and Vale of Yorkshire are remarkable for the quantities of honey they produce; but it is of an inferior quality, owing, as Mr Marshall supposes, to the heath. He observes, that in the hives situated between the heaths and cultivated country, there is a remarkable difference between the vernal and autumnal combs. The former, gathered entirely from the meadows, pasture-lands, trees, and cultivated crops, are in a manner as white as snow; the latter brown, and the honey rather like melted rosin than the pure limpid consistence of the former.—In the winter of 1782, a remarkable mortality took place among the bees of this district; vast numbers of hives perishing gradually, though plenty of honey remained. The phenomenon appeared unaccountable; but Mr Marshall explains it with some probability, from a want of what is called *bee-bread*, and which the bees collect from the farina of the flowers, as they do the honey and wax from the nectarium and pistillum. The farina cannot be obtained until the antheræ are burst by the sun, which, in the very cold rainy season of 1782, could not be expected, as the influence of the sun was not only very small, but the farina, when once collected, was liable to be washed away by the rains. Hence, while the bread which the bees had collected in small quantity lasted, they continued to live; but when this was exhausted, they gradually perished one after another; for it is now universally allowed, that without bee-bread the life of these insects cannot be sustained, even though they have plenty of honey.

Bath Papers, vol. 5.
205
Mr Key's observations.

In a paper on the subject of bees by Mr John Keys, the farina is supposed to be useful for nourishing the young brood, and the honey for the support of the old ones: hence, according to the quantity of farina to be procured the stock of bees is limited. In the place where he resided at the time his letter was wrote (near Pembroke), no more than eight hives could be kept by a single person with propriety; but at Cheshunt in Herefordshire, where he resided before, he could keep 12 or 14. In his opinion, none but the good first swarms ought to be preserved; the after-swarms should be returned to the stock, by which means the increase of honey would be much greater. “An incorporated stock (he says) will gather more honey than three or four single ones.” Hives of half a bushel measure ought to weigh 20 pounds at least, and larger hives in proportion; and they ought not to be above two years of age. He laments it as a national loss, that great part of the prime swarms are suffered to escape, from an erroneous opinion about signs and hours of swarming; “whereas nothing less than a *constant* watching, from seven to four, can prevent this loss, but which the peasantry will not comply with.” Mr Keys has in vain attempted to find an easy method of swarming them artificially.—For the general method of managing bees, see the articles *APIS* and *BEE*.

SECT. IX. *Of the Management of the Dairy.*

As this includes not only the proper method of preserving milk in a wholesome and uncorrupted state, but

the making of butter and cheese from it, it may deservedly be accounted as important a part of husbandry as any; and accordingly several treatises have been written expressly upon the subject.

Management of the Dairy.

In the fifth volume of Bath Papers, the subject seems to be considered in as accurate and scientific a manner by Dr Anderson as by any person who has treated this matter; at least as far as regards the making of butter. The requisites for manufacturing this valuable commodity, according to him, are the following:

1. *To have cows of a good quality.* In this we are to attend more to the quantity of cream which the milk of a cow yields, than to the absolute quantity of milk; and this may commonly be judged of from the thickness of it. The small Alderney cows (he says) afford the richest milk hitherto known; though there are many individuals of different kinds which afford much richer milk than others; and these ought carefully to be sought after, that a good breed may be established.

2. *To make the cows yield a large quantity of milk.* For this purpose they must have plenty of food; and of all other kinds the Doctor determines grass to be the best; and that grass which springs up spontaneously on rich dry soils to be the best of all. He is of opinion, however, that there is no virtue in *old* pastures, as many suppose, more than in *new* ones; and he assures us, that he has seen much richer butter made from the milk of cows fed upon hay from clover and rye-grass in the house, than such as had liberty to range in old pastures. He thinks, however, that the cows should be permitted to pasture at pleasure during the mornings and evenings, but at noon should be taken into a house, and supplied with fresh food. If abundantly fed, they should be milked three times a day; and as great care should be taken that this operation be properly performed, only confidential persons should be employed. He supposes that a cow well fed, will give as much milk each time when milked thrice, as when milked only twice.

3. *The qualities of the milk itself.* These are reduced by our author to the following aphorisms. 1. Of the milk drawn from a cow at any time, that which comes first is always thinnest, and continues to increase in thickness to the very last drop. This, as well as all the succeeding ones, are proved by experiment; and so great is the importance of attending to it, that “the person who, by bad milking of his cows, loses but half a pint of his milk, loses, in fact, as much cream as would be afforded by six or eight pints at the beginning, and loses besides that part of the cream which alone can give richness and high flavour to his butter.” 2. When milk throws up cream to the surface, that portion which rises first will be thicker, and of better quality, as well as in greater quantity, than that which rises in a second equal portion of time. 3. Thick milk throws up a smaller quantity of cream to the surface than such as is thinner; but that cream is of a richer quality. If water be added to that thick milk, it will afford a considerably greater quantity of cream than before, but its quality is at the same time greatly debased. 4. Milk when carried in vessels to any distance, so as to suffer considerable agitation, never throws up cream so rich, nor in such quantity, as if the same had been put into the milk-pans without any agitation. From these aphorisms, the following corollaries are deducible. 1. The cows ought always

209
Dairy de-
scribed.

to be milked as near the dairy as possible. 2. The milk of different cows should be kept by themselves, that the good cows may be distinguished from the bad. 3. For butter of a very fine quality, the first drawn milk ought always to be kept separate from the last.

Our author now commends the method used by the Highlanders of Scotland, where every cow is allowed to suckle her own calf. The calves are kept in an inclosure till the time of milking, when they are allowed to come to the door. Each calf there is allowed to suck its dam as long as the milk-maid pleases; when it is driven away, and the woman milks the remainder. Thus they obtain only a small quantity of milk, but of exceeding good quality; and to this practice Dr Anderson ascribes the richness of the Highland butter, which is usually attributed to the old grass in the remote glens of the Highlands. In places where this practice cannot be economically followed, the Doctor recommends to keep the milk which comes first, and that which comes last, separate from each other. The former might be sold sweet, or made into cheese. Another use our author mentions, viz.

“Take common skimmed milk when it begins to turn sour; put it into an upright churn or barrel with one of its ends out, or any other convenient vessel; heat some water, and pour it into a tub that is large enough to contain with ease the vessel in which the milk was put. Set the vessel containing the milk into the hot water, and let it remain there for the space of one night. In the morning it will be found that the milk hath separated into two parts; a thick cream-like substance which occupies the upper part of the vessel, and a thin, serous, watery part that remains in the bottom: draw off the thin part (called here *swigg*), by opening a stop-cock placed for that purpose close above the bottom, and reserve the cream for use. Not much less than the half of the milk is thus converted into a sort of cream, which when well made seems to be as rich and fat as real cream itself, and is only distinguishable from that by its sourness. It is eaten with sugar, and esteemed a great delicacy; and usually sells at double the price of unskimmed milk.” 4. Besides separating the first from the last drawn milk, it will be necessary also to take nothing but the cream first separated from the best milk. The remainder of the milk may be employed either in making cheeses, or allowed to throw up cream for butter of an inferior quality. 5. Hence it is plain, that butter of the very best quality, could be made only in a dairy of considerable extent, as only a small portion of the milk of each cow could be set apart for it. 6. Hence it appears that butter and cheese can be made in a consistency with one another; the best of the milk being set apart for the former, and the worst for the latter. But as perhaps no person would choose to give such a price for the very best butter as would indemnify the farmer for his trouble and expence, it may be sufficient to take only the first drawn half of the milk for cheese, and use the remainder for butter; and the cream of this, even though allowed to stand till it begins to turn sour, will always yield butter of a much superior quality to that produced in the ordinary manner.

Our author now proceeds to enumerate the properties of a dairy. The milk-house ought to be cool in

summer and warm in winter; so that an equal temperature may be preserved throughout the year. It ought also to be dry, so as to admit of being kept sweet and clean at all times. A separate building should be erected for the purpose, near a cool spring or running water, where the cows may have easy access to it, and where it is not liable to be incommoded by stagnant water. The apartment where the milk stands should be well thatched, have thick walls, and a ventilator in the top for admitting a free circulation of air. There should also be an apartment with a fire-place and cauldron, for the purpose of scalding and cleaning the vessels. The Doctor is of opinion, that the temperature of from 50 to 55 degrees is the most proper for separating the cream from the milk, and by proper means this might easily be kept up, or nearly so, both summer and winter.

The utensils of the dairy should be all made of wood, in preference either to lead, copper, or even cast iron. These metals are all very easily soluble in acids; the solutions of the two first highly poisonous; and though the latter is innocent, the taste of it might render the products highly disagreeable. The creaming dishes, when properly cleaned, sweet, and cool, ought to be filled with the milk as soon as it is drawn from the cow, having been first carefully strained through a cloth, or close strainer made of hair or wire: the Doctor prefers silver wire to every other. The creaming dishes ought never to exceed three inches in depth; but they may be so broad as to contain a gallon or a gallon and an half; when filled they ought to be put on the shelves of the milk-house, and remain there until the cream be fully separated. If the finest butter be intended, the milk ought not to stand above six or eight hours, but for ordinary butter it may stand twelve hours or more; yet if the dairy be very large, a sufficient quantity of cream will be separated in two, three, or four hours, for making the best butter. It is then to be taken off as nicely as possible by a skimming-dish, without lifting any of the milk; and immediately after put into a vessel by itself, until a proper quantity for churning be collected. A firm, neat, wooden barrel seems well adapted for this purpose, open at one end, and having a lid fitted to close it. A cock or spigot ought to be fixed near the bottom, to draw off any thin or serous part which may drain from the cream; the inside of the opening should be covered with a bit of fine silver wire gauze, in order to keep back the cream while the serum is allowed to pass; and the barrel should be inclined a little on its stand, to allow the whole to run off.

The Doctor contradicts the opinion that very fine butter cannot be obtained, except from cream that is not above a day old. On the contrary, he insists that it is only in very few cases that even tolerably good butter can be obtained from cream that is not above one day old. The separation of butter from cream only takes place after the cream has attained a certain degree of acidity. If it be agitated before that acidity has begun to take place, no butter can be obtained, and the agitation must be continued till the time that the sourness is produced; after which the butter begins to form. “In summer, while the climature is warm, the heating may be, without very much difficulty, continued until the acidity be produced,

Manage-
ment of the
Dairy.

duced, so that butter may be got: but in this case the process is long and tedious; and the butter is for the most part of a soft consistence, and tough and gluey to the touch. If this process be attempted during the cold weather in winter, butter can scarcely be in any way obtained, unless by the application of some great degree of heat, which sometimes assists in producing a very inferior kind of butter, white, hard, and brittle, and almost unfit for any culinary purpose whatever. The judicious farmer, therefore, will not attempt to imitate this practice, but will allow his cream to remain in the vessel appropriated for keeping it, until it has acquired the proper degree of acidity. There is no rule for determining how long it is to be kept; but our author is of opinion that a very great latitude is allowable in this case; and that if no ferous matter be allowed to lodge among the cream, it may be kept good for making butter a great many weeks.

212
Of the
churn.

The churn in which butter is made likewise admits of considerable diversity; but our author prefers the old-fashioned upright churn to all others, on account of its being more easily cleaned. The labour, when the cream is properly prepared, he thinks, very trifling. Much greater nicety, he says, is required in the process of churning than most people are aware of; as a few hasty and irregular strokes will render butter bad, which otherwise would have been of the finest quality. After the process is over, the whole ought to be separated from the milk, and put into a clean dish; the inside of which, if made of wood, ought to be well rubbed with common salt, to prevent the butter from adhering to it. The butter should be pressed and worked with a flat wooden laddle or skimming dish, having a short handle, so as to force out all the milk that was lodged in the cavities of the mass. This operation requires a considerable degree of strength as well as dexterity; but our author condemns the beating up of the butter with the hand as "an indelicate and barbarous practice." In like manner he condemns the employing of cold water in this operation, to *wash* the butter as it is called. Thus, he says, the quality of it is debased in an astonishing degree. If it is too soft, it may be put into small vessels, and these allowed to swim in a tub of cold water; but the water ought never to touch the butter. The beating should be continued till the milk be thoroughly separated, but not till the butter become tough and gluey; and after this is completely done, it is next to be salted. The vessel into which it is to be put must be well seasoned with boiling water several times poured into it; the inside is to be rubbed over with common salt, and a little melted butter poured into the cavity between the bottom and sides, so as to make it even with the bottom; and it is then fit for receiving the butter. Instead of common salt alone, the Doctor recommends the following composition. "Take of sugar one part, of nitre one part, and of the best Spanish great salt two parts. Beat the whole into a fine powder, mix them well together, and put them by for use. One ounce of this is to be thoroughly mixed with a pound of butter as soon as it is freed from the milk, and then immediately put into the vessel designed to hold it; after which it must be pressed so close as to leave no air-holes; the surface is to be smoothed and

tion for
preserving
butter.

covered with a piece of linen, and over that a piece of wet parchment; or in defect of this last, fine linen that has been dipped in melted butter, exactly fitted to the edges of the vessel all round, in order to exclude the air as much as possible. When quite full, the cask is to be covered in like manner, and a little melted butter put round the edges, in order to fill up effectually every cranny, and totally to exclude the air. "If all this (says the Doctor) be carefully done, the butter may be kept perfectly sound in this climate for many years. How many years I cannot tell; but I have seen it two years old, and in every respect as sweet and sound as when only a month old. It deserves to be remarked, that butter cured in this manner does not taste well till it has stood at least a fortnight after being salted; but after that period is elapsed, it eats with a rich marrowy taste that no other butter ever acquires; and it tastes so little salt, that a person who had been accustomed to eat butter cured with common salt only, would not imagine it had got one-fourth part of the salt necessary to preserve it." Our author is of opinion, that strong brine may be useful to pour upon the surface during the time it is using, in order the more effectually to preserve it from the air, and to avoid rancidity.

As butter contains a quantity of mucilaginous matter much more putrescible than the pure oily part, our author recommends the purifying it from this muckage, by melting in a conical vessel, in which the muckage will fall to the bottom; the pure oily part swimming at top. This will be useful when butter is to be sent a long voyage to warm climates, as the pure part will keep much better than when mixed with the other. He proposes another method of preserving butter, *viz.* by mixing it with honey, which is very antiseptic, and mixes intimately with the butter. Thus mixed, it eats very pleasantly, and may perhaps be successfully used with a medicinal intention.

The other grand object of the dairy is cheese-making, which in some counties of England becomes a very considerable article. In this the same precaution is to be observed as with regard to butter; *viz.* the milk ought not to be agitated by carrying to any distance; nor ought the cows to be violently driven before they are milked, which reduces the milk almost to the same state as if agitated in a barrel or churn. To this cause Mr Twamley, who has written a treatise upon dairy management, attributes the great difficulty sometimes met with in making the milk coagulate; four or five hours being sometimes necessary instead of one (the usual time employed); and even after all, the curd will be of such a soft nature, that the cheese will swell, puff up, and rent in innumerable places without ever coming to that solid consistence which it ought to have. As this frequently happens in consequence of heat, Mr Twamley advises to mix a little cold spring-water with the milk. It is a bad practice to put in more rennet when the curd appears difficult to be formed; for this, after having once formed the curd by the use of a certain quantity, will dissolve it again by the addition of more.

The most common defects of cheese are its appearing when cut full of small holes called *eyes*; its puffing up, cracking, and pouring out quantities of thin serous liquor;

ceipt for
runnet.

liquor; becoming afterwards rotten and full of mag-
gots in those places from which the liquor issued. All
this, according to our author, proceeds from the for-
mation of a substance called by him *slip curd*, a kind of
half coagulum, incapable of a thorough union with the
true curd, and which when broken into very small bits
produces *eyes*; but if in larger pieces, occasions those
rents and cracks in the cheese already mentioned; for
though this kind of curd retains its coagulated nature
for some time, it always sooner or later dissolves into
a ferous liquid. This kind of curd may be produced,
1. By using the milk too hot. 2. By bad runnet.
3. By not allowing the curd a proper time to form.
The first of these is remedied by the use of cold water,
which our author says is so far from being detrimental
to the quality of the cheese, that it really promotes
the action of the runnet upon the milk. The second,
viz. a knowledge of good from bad runnet, can only
be acquired by long practice, and no particular direc-
tions can be given, farther than that the utmost care
must be taken that it have no putrid tendency, nor
any rancidity from too great heat in drying. The
only rule that can be given for its preparation is to
take out the maw of a calf which has fed entirely upon
milk; after it is cold, swell it a little in water; rub it
well with salt; then fill it with the same, and after-
wards cover it. Some cut them open and spread them
in salt, putting them in layers above one another, let-
ting them continue in the brine they produce, some-
times stirring or turning them for four, six, or nine
months; after which they are opened to dry, stretch-
ed out upon sticks or splints. They may be used im-
mediately after being dried, though it is reckoned best
to keep them till they be a year old before they are
used. The best method of making the runnet from
the skins, according to our author, is the following:
"Take pure spring-water, in quantity proportioned
to the runnet you intend to make; it is thought best
by some two skins to a gallon of water; boil the wa-
ter, which makes it softer or more pure; make it
with salt into brine that will swim an egg; then let it
stand till the heat is gone off to about the heat of
blood-warm; then put your maw-skin in, either cut
in pieces or whole; the former I should imagine best
or most convenient; letting it steep 24 hours, after
which it will be fit for use. Such quantity as is
judged necessary must then be put into the milk; about
a tea-cupful being necessary for ten cows milk; though
in this respect very particular directions cannot be
given."

In the Bath Papers, Mr Hazard gives the following
receipt for making runnet. "When the maw-skin is
well prepared and fit for the purpose, three pints or
two quarts of soft water, clean and sweet, should be
mixed with salt, wherein should be put sweet brier,
rose-leaves and flowers, cinamon mace, cloves, mace,
and in short almost every sort of spice and aromatic
that can be procured; and if these are put into two
quarts of water, they must boil gently till the liquor
is reduced to three pints, and care should be taken that
this liquid is not smoked; it should be strained clear
from the spices, &c. and when found not to be warm-
er than milk from the cow, it should be poured upon
the vell or maw; a lemon may then be sliced into it,

when it may remain a day or two; after which it
should be strained again and put into a bottle, where if
well corked it will keep good for twelve months or
more; it will smell like a perfume, and a small quan-
tity of it will turn the milk and give the cheese a
pleasing flavour." He adds, that if the vell or maw
be salted and dried for a week or two near the fire, it
will do for the purpose again almost as well as before.

In the making of cheese, supposing the runnet to
be of a good quality, the following particulars must
be observed: 1. The proper degree of heat. This
ought to be what is called *milk-warm*, or "a few
degrees removed from coolness," according to Mr
Twamley; considerably below the heat of milk taken
from the cow. If too hot, it may be reduced to
a proper temperature by cold water, as already
mentioned. 2. The time allowed for the runnet
to take effect. This, our author observes, ought
never to be less than an hour and a half. The process
may be accelerated, particularly by putting salt to the
milk before the runnet is added. Mr Twamley ad-
vises two handfuls to ten or twelve cows milk; but he
assures us, that no bad consequence can follow from
the curd being formed ever so soon; as it then only
becomes more solid and fit for making cheese of a pro-
per quality. 3. To prevent any difficulty in separa-
ting the curd from the whey, prepare a long cheese
knife from lath; one edge being sharpened to cut the
curd across from top to bottom in the tub, crossing it
with lines checkerwise; by which means the whey
rises through the vacancies made by the knife, and the
curd sinks with much more ease. A sieve has also
been used with success, in order to separate the whey
perfectly from the curd. 4. Having got the curd all
firm at the bottom of the tub, take the whey from it;
let it stand a quarter of an hour to drain before you
put it into the vat to break it. If any bits of slip-curd
swim among the whey, pour it all off together rather
than put it among the cheese, for the reasons already
given. Some dairy-women allow the curd to stand
for two hours; by which time it is become of so firm
a nature, that no breaking is necessary: they have only
to cut it in slices, put it into the vat, and work it well
by squeezing thoroughly to make it sit close; then
put it into the press. Our author, however, approves
more of the method of breaking the curd, as less apt
to make the cheese hard and horny. 5. When the
whey is of a white colour, it is a certain sign that the
curd has not subsided; but if the method just now laid
down be followed, the whey will always be of a green
colour; indeed this colour of the whey is always a cer-
tain criterion of the curd having been properly managed.
6. The best method of preventing cheese from heaving,
is to avoid making the runnet too strong, to take care
that it be clean, and not tainted; to be certain that the
curd is fully come, and not to stir it before the air has
had time to escape; a quantity of air being always dis-
charged in this as in many other chemical processes.
7. Cheese is very apt to split in consequence of being
"salted within," especially when the vat is about half
filled. In this case the curd, though separated only in
a small degree by the salt, never closes or joins as it
ought to do. Mr Twamley prefers salting in the milk
greatly to this method. 8. Dry cracks in cheese are
before

cheese.

Fruit Li-
quors.

generally produced by keeping curd from one meal to another, and letting the first become too stiff and hard before it is mixed with the other. 9. Curdly or wrinkle-coated cheese is caused by sour milk. Cheese made of cold milk is apt to be hard, or to break and fly before the knife. 10. Such coated cheese is caused by being made too cold, as cheese that is made in winter or late in autumn is apt to be, unless laid in a warm room after it is made.

222
Different
kinds of
cheese.

Cheese is of very different quality, according to the milk from which it is made: Thus, in Gloucestershire, what is called the *second* or *two-meal* cheese, is made from one meal of new milk and one of skimmed or old milk, having the cream taken away. Skimmed cheese, or *flat milk* cheese, is made entirely from skimmed milk, the cream having been taken off to make butter. It goes by the name of *Suffolk cheese*, and is much used at sea; being less liable to be affected by the heat of warm climates than the other kinds. A great deal of difference, however, is to be observed in the quality of it, which our author supposes to arise chiefly from greater care being taken in some places than in others.

Slip coat or soft cheese is made entirely of slip-curd, and dissolves into a kind of creamy liquor; which is a demonstration of the nature of this curd as already mentioned. It is commonly computed, that as much milk is required to make one pound of butter as two of cheese; and even more where the land is poor, and the pastures afford but little cream.—For further particulars with regard to these two commodities, see the articles BUTTER and CHEESE.

SECT. X. Making of Fruit-Liquors.

THESE, as objects of British husbandry, are principally two, *Cyder* and *Perry*; the manufacturing of which forms a capital branch in our fruit-counties, and of which the improvement must be considered as of great importance to the public, but particularly so to the inhabitants of those districts where these liquors constitute their common beverage.

223
Excellence
of cyder and
perry.

Cyder and perry, when genuine and in high perfection, are excellent vinous liquors, and are certainly far more wholesome than many others which at present are in much higher estimation. When the must is prepared from the choicest fruit, and undergoes the exact degree of vinous fermentation requisite to its perfection, the acid and the sweet are so admirably blended with the aqueous, oily, and spiritous principles, and the whole so imbued with the grateful flavour of the rinds, and the agreeable aromatic bitter of the kernels, that it assumes a new character; grows lively, sparkling, and exhilarating; and when completely mellowed by time, the liquor becomes at once highly delicious to the palate, and congenial to the constitution; superior in every respect to most other English wines, and perhaps not inferior to many of the best foreign wines. Such (says Dr Fothergill†) would it be pronounced by all competent judges, were it not for the popular prejudice annexed to it as a cheap home-brewed liquor, and consequently within the reach of the vulgar. To compare such a liquor with the foreign fiery sophisticated mixtures often imported under the name of wines, would be to degrade it; for

† Bath Pa-
pers, vol. v.
p. 343.

it certainly surpasses them in flavour and pleasantness, as much as it excels them in wholesomeness and cheapness. But rarely do we meet with perry or cyder of this superior quality. For what is generally sold by dealers and inn-keepers is a poor, meagre, vapid liquor, prone to the acetous fermentation, and of course very injurious to the constitution. Is it not very mortifying, after the experience of so many centuries, that the art of preparing those ancient British liquors should still be so imperfectly understood as yet to seem to be in its very infancy?—That throughout the principal cyder districts, the practice should still rest on the most vague indeterminate principles, and that the excellence of the liquor should depend rather on a lucky random hit, than on good management! Yet such appears to be really the case even among the most experienced cyder-makers of Herefordshire and Gloucestershire.

Mr Marshall, that nice observer of rural affairs, in his late tour* through those counties (expressly undertaken for the purpose of inquiry on this subject), informs us, that scarcely two of these professional artists are agreed as to the management of some of the most essential parts of the process. That palpable errors are committed as to the time and manner of gathering the fruit—in laying it up—in neglecting to separate the unsound—and to grind properly the rinds and kernels, &c. That the method of conducting the vinous fermentation, the most critical part of the operation, and which stamps the future value of the liquor, is by no means ascertained: While some promote the fermentation in a spacious open vat, others repress it by inclosing the liquor in a hoghead, or strive to prevent it altogether. That no determinate point of temperature is regarded, and that the use of the thermometer is unknown or neglected. That they are as little consistent as to the time of racking off; and whether this ought to be done only once, or five or six times repeated. That for fining down the liquor, many have recourse to that odious article, bullock's blood, when the intention might be much better answered by whites of eggs or isinglass. And, finally, that the capricious taste of particular customers is generally consulted, rather than the real excellence of the liquor; and consequently that a very imperfect liquor is often vended, which tends to reduce the price, to disgrace the vender, and to bring the use of cyder and perry into disrepute.

The art of making vinous liquors is a curious chemical process; and its success chiefly depends on a dexterous management of the vinous fermentation, besides a close attention to sundry minute circumstances, the theory of which is perhaps not yet fully understood by the ablest chemists. Can we longer wonder then that so many errors should be committed by illiterate cyder-makers, totally unversed in the first principles of the chemical art? Some few, indeed, more enlightened than their brethren, and less bigotted to their own opinions, by dint of observation strike out improvements, and produce every now and then a liquor of superior quality, though perhaps far short of excellence, yet still sufficient to show what might possibly be accomplished by a series of new experiments conducted on philosophical principles. This might lead

to successive improvements, till at length our English fruit-liquors might be carried to a pitch of perfection hitherto unknown, by which the demand, both at home and abroad, would soon be enlarged, the prices augmented according to the quality, the value of estates increased, and the health and prosperity of these counties proportionably advanced. This might also help to point out a method of correcting the imperfections of these liquors; and of meliorating those of a weak meagre quality, by safer and more effectual means than are now practised: and though nothing can fully compensate the defect of sunshine in maturing the saccharine juices in unfavourable seasons, yet probably such liquor might, without the dangerous and expensive method of boiling in a copper vessel, admit of considerable improvement by the addition of barm or other suitable ferment, as yet unknown in the practice of the cyder districts; or perhaps rather by a portion of rich must, or some wholesome sweet, as honey, sugar-candy, or even mellasses, added in due proportion, previous to the fermentation. In fact, it appears from a late publication†, that the Germans are known to meliorate their thin harsh wines by an addition of concentrated must, not by evaporation, but by freezing. By this simple process they are made to emulate good French wines; a practice worthy of imitation, especially in the northern climates.

Cyder, as is well known, is made from apples, and *Perry* from pears only. The general method of preparing both these liquors is very much the same; and under the article *CYDER* a description is given of the way in which those fruits are gathered, ground, and pressed. The mill is not essentially different from that of a common tanner's mill for grinding bark. It consists of a mill-stone from two and an half to four feet and an half in diameter, running on its edge in a circular stone trough, from nine to twelve inches in thickness, and from one to two tons in weight. The bottom of the trough in which this stone runs is somewhat wider than the thickness of the stone itself; the inner side of the groove rises perpendicularly, but the outer spreads in such a manner as to make the top of the trough six or eight inches wider than the bottom; by which means there is room for the stone to run freely, and likewise for putting in the fruit, and stirring it up while grinding. The bed of a middle-sized mill is about 9 feet, some 10, and some 12; the whole being composed of two, three, or four stones cramped together, and finished after being cramped in this manner. The best stones are found in the forest of Dean; generally a dark, reddish gritstone, not calcareous; for if it were of a calcareous quality, the acid juice of the fruits would act upon it and spoil the liquor: a clean-grained grindstone grit is the fittest for the purpose. The runner is moved by means of an axle passing through the centre, with a long arm reaching without the bed of the mill, for a horse to draw by; on the other side is a shorter arm passing through the centre of the stone, as represented in the figure. An iron bolt, with a large head, passes through an eye, in the lower part of the swivel on which the stone turns, into the end of the inner arm of the axis; and thus the double motion of it is ob-

tained, and the stone kept perfectly upright. There ought also to be fixed on the inner arm of the axis, about a foot from the runner, a cogged wheel working in a circle of cogs, fixed upon the bed of the mill. The use of these is to prevent the runner from sliding, which it is apt to do when the mill is full; it likewise makes the work more easy for the horse. These wheels ought to be made with great exactness. Mr Marshall observes, that it is an error to make the horse draw by traces: "The acting point of draught (says he), the horse's shoulder, ought, for various reasons, to be applied immediately at the end of the arm of the axis; not two or three yards before it; perhaps of a small mill, near one fourth of its circumference." The building in which the mill is inclosed ought to be of such a size, that the horse may have a path of three feet wide betwixt the mill and the walls; so that a middling-sized mill, with its horse-path, takes up a space of 14 or 15 feet every way. The whole dimensions of the mill-house, according to our author, to render it any way convenient, are 24 feet by 20: it ought to have a floor thrown over it at the height of seven feet; with a door in the middle of the front, and a window opposite, with the mill on one side and the press on the other side of the window. The latter must be as near the mill as convenience will allow, for the more easy conveying the ground fruit from the one to the other. The press, of which the principle will be understood from the figure, has its bed or bottom about five feet square. This ought to be made entirely either of wood or stone; the practice of covering it with lead being now universally known to be pernicious. It has a channel cut a few inches within its outer edges, to catch the liquor as it is expressed, and convey it to a lip formed by a projection on that side of the bed opposite to the mill; having under it a stone trough or wooden vessel, sunk within the ground, when the bed is fixed low, to receive it. The press is worked with levers of different lengths; first a short, and then a moderately long one, both worked by hand; and lastly, a bar eight or nine feet long worked by a capstane or windlass. The expence of fitting up a mill-house is not very great. Mr Marshall computes it from 20l. to 25l. and, on a small scale, from 10l. to 15l. though much depends on the distance and carriage of the stone: when once fitted up, it will last many years.

The making of the fruit-liquors under consideration requires an attention to the following particulars. I. The fruit. II. The grinding. III. Pressing. IV. Fermenting. V. Correcting. VI. Laying up. VII. Bottling; each of which heads is subdivided into several others.

I. In the *management of the fruit*, the following particulars are to be considered.

1. The time of gathering; which varies according to the nature of the fruit. - The early pears are fit for the mill in September; but few apples are ready for gathering before Michaelmas; though, by reason of accidental circumstances, they are frequently manufactured before that time. For sale cyder, and keeping drink, they are suffered to hang upon the trees till fully ripe; and the middle of Octo-

ber.

228
Manage-
ment of the
fruit.

Fruit Li-
quor.

ber is generally looked upon to be a proper time for gathering the fire-apple. The criterion of a due degree of ripeness is the fruit falling from the tree; and to force it away before that time, in Mr Marshall's opinion, is robbing it of some of its most valuable particles. "The harveſting of fruit (ſays he) is widely different in this reſpect from the harveſting of grain; which has the entire plant to feed it after its ſeparation from the ſoil; while fruit, after it is ſevered from the tree, is cut off from all poſſibility of a further ſupply of nourishment; and although it may have reached its wonted ſize, ſome of its more eſſential particles are undoubtedly left behind in the tree." Sometimes, however, the fruits which are late in ripening are apt to hang on the tree until ſpoiled by froſts; though weak watery fruits ſeem to be moſt injured in this manner; and Mr Marshall relates an inſtance of very fine liquor being made from golden pippins, after the fruit had been frozen as hard as ice.

229
Method of
gathering
it.

2. The method of gathering. This, as generally practiſed, is directly contrary to the principle laid down by Mr Marshall, viz. beating them down with long ſlender poles. An evident diſadvantage of this method is, that the fruit is of unequal ripeneſs; for the apples on the ſame trees will differ many days, perhaps even weeks, in their time of coming to perfection; whence ſome part of the richneſs and flavour of the fruit will be effectually and irremediably cut off. Nor is this the only evil to be dreaded; for as every thing depends on the fermentation it has to undergo, if this be interrupted, or rendered complex by a mixture of ripe and unripe fruits, and the liquor be not in the firſt inſtance ſufficiently purged from its ſeculencies, it is difficult to clear the liquor afterwards. The former defect the cyder makers attempt to remedy by a mixture of brown ſugar and brandy, and the latter by bullock's blood and brimſtone; but neither of theſe can be expected to answer the purpoſe very effectually. The beſt method of avoiding the inconveniences ariſing from an unequal ripening of the fruit is to go over the trees twice, once with a hook, when the fruit begins to fall ſpontaneously; the ſecond time, when the latter are ſufficiently ripened, or when the winter is likely to ſet in, when the trees are to be cleared with the poles above-mentioned.

230
Maturing
it, &c.

3. Maturing the gathered fruit. This is uſually done by making it into heaps, as is mentioned under the article CYDER: but Mr Marshall entirely diſapproves of the practice; becauſe, when the whole are laid in a heap together, the ripeſt fruit will begin to rot before the other has arrived at that degree of artificial ripeneſs which it is capable of acquiring. "The due degree of maturation of fruit for liquor (he obſerves) is a ſubject about which men, even in this diſtrict, differ much in their ideas. The prevailing practice of gathering into heaps until the ripeſt begin to rot, is waſting the beſt of the fruit, and is by no means an accurate criterion. Some ſhake the fruit, and judge by the rattling of the kernels; others cut through the middle, and judge by their blackneſs; but none of theſe appear to be a proper teſt. It is not the ſtate of the kernels but of the fleſh; not of a few individuals, but of the greater part of the prime-fruit, which renders the collective body fit or unfit to be ſent to the mill. The moſt rational teſt of the ripeneſs of the fruit, is that of the fleſh

N^o 160.

having acquired ſuch a degree of mellowneſs, and its texture ſuch a degree of tenderneſs, as to yield to moderate preſſure. Thus, when the knuckle or the end of the thumb can with moderate exertion be forced into the pulp of the fruit, it is deemed in a fit ſtate for grinding."

4. Preparation for the mill. The proper management of the fruit is to keep the ripe and unripe fruit ſeparate from each other; but this cannot be done without a conſiderable degree of labour; for as by numberleſs accidents the ripe and unripe fruits are frequently confounded together, there cannot be any effectual method of ſeparating them except by hand; and Mr Marshall is of opinion, that this is one of the grand ſecrets of cyder-making, peculiar to thoſe who excel in the buſineſs; and he is ſurpriſed that it ſhould not before this time have come into common practice.

5. Mixing fruits for liquor. Our author ſeems to doubt the propriety of this practice; and informs us, that the finer liquors are made from ſelect fruits; and he hints that it might be more proper to mix liquors after they are made, than to put together the crude fruits.

II. Grinding, and management of the fruit when ground.

1. For the greater convenience of putting the fruit into the mill, every mill-houſe ſhould have a fruit-chamber over it, with a trap-door to lower the fruit down into the mill. The beſt manner in which this can be accompliſhed, is to have the valve over the bed of the mill, and furniſhed with a cloth ſpout or tunnel reaching down to the trough in which the ſtone moves. No ſtraw is uſed in the loſts, but ſometimes the fruit is turned. In Herefordſhire, it is generally believed, that grinding the rind and ſeeds of the fruit as well as the fleſhy part to a pulp, is neceſſary towards the perfection of the cyder; whence it is neceſſary, that every kind of pains ſhould be taken to perform the grinding in the moſt perfect manner. Mr Marshall complains, that the cyder-mills are ſo imperfectly finiſhed by the workmen, that for the firſt fifty years they cannot perform their work in a proper manner. Inſtead of being nicely fitted to one another with the ſquare and chiffeſel, they are hewn over with a rough tool in ſuch a careleſs manner, that horſe-beans might lie in ſafety in their cavities. Some even imagine this to be an advantage, as if the fruit was more effectually and completely broken by rough than ſmooth ſtones. Some uſe fluted rollers of iron; but theſe will be corroded by the juice, and thus the liquor might be tinged. Smooth rollers will not lay hold of the fruit ſufficiently to force it through.

Another improvement requiſite in the cyder-mills is to prevent the matter in the trough from riſing before the ſtone in the laſt ſtage of grinding, and a method of ſtirring it up in the trough more effectually than can be done at preſent. To remedy the former of theſe defects, it might perhaps be proper to grind the fruit firſt in the mill to a certain degree; and then put it between two ſmooth rollers to finiſh the operation in the moſt perfect manner. It is an error to grind too much at once; as this clogs up the mill, and prevents it from going eaſily. The uſual quantity for a middleſized mill is a bag containing four corn buſhels: but our author had once an opportunity of ſeeing a mill

in

Fruit-Liquors

in which only half a bag was put; and thus the work seemed to go on more easily as well as more quickly than when more was put in at once. The quantity put in at one time is to be taken out when ground. The usual quantity of fruit ground in a day is as much as will make three hogsheds of perry or two of cyder.

2. Management of the ground-fruit. Here Mr Marshall condemns in very strong terms the practice of pressing the pulp of the fruit as soon as the grinding is finished; because thus neither the rind nor seeds have time to communicate their virtues to the liquor. In order to extract these virtues in the most proper manner, some allow the ground-fruit to lie 24 hours or more after grinding, and even regrind it, in order to have in the most perfect manner the flavour and virtues of the seeds and rind.

232
Pressing,
&c.

III. *Pressing the fruit, and management of the residuum.* This is done by folding up the ground-fruit in pieces of hair-cloth, and piling them up above one another in a square frame or mould, and then pulling down the press upon them, which squeezes out the juice, and forms the matter into thin and almost dry cakes. The first runnings come off foul and muddy; but the last, especially in perry, will be as clear and fine as if filtered thro' paper. It is common to throw away the residuum as useless; sometimes it is made use of when dry as fuel; sometimes the pigs will eat it, especially when not thoroughly squeezed; and sometimes it is ground a second time with water, and squeezed for an inferior kind of liquor used for the family. Mr Marshall advises to continue the pressure as long as a drop can be drawn. "It is found (says he), that even by breaking the cakes of refuse with the hands only gives the press fresh power over it; for though it has been pressed to the last drop, a gallon or more of additional liquor may be got by this means. Regrinding them has a still greater effect: In this state of the materials the mill gains a degree of power over the more rigid parts of the fruit, which in the first grinding it could not reach. If the face of the runner and the bottom of the trough were dressed with a broad chissel, and made true to each other, and a moderate quantity of residuum ground at once, scarcely a kernel could escape unbroken, or a drop of liquor remain undrawn."

But though the whole virtue of the fruit cannot be extracted without grinding it very fine, some inconvenience attends this practice, as part of the pulp thus gets through the hair cloth, and may perhaps be injurious to the subsequent fermentation. This, however, may be in a great measure remedied by straining the first runnings through a sieve. The whole should also be allowed to settle in a cask, and drawn off into a fresh vessel previous to the commencement of the fermentation. The reduced fruit ought to remain some time between the grinding and pressing, that the liquor may have an opportunity of forming an extract with the rind and kernels: but this must not be pushed too far, as in that case the colour of the cyder would be hurt; and the most judicious managers object to the pulp remaining longer than 12 hours without pressure. "Hence (says our author), upon the whole, the most eligible management in this stage of the art appears to be this: Grind one pressful a-day; press

VOL. VIII. Part II.

and regrind the residuum in the evening; infuse the reduced matter all night among part of the first runnings; and in the morning re-press while the next pressful is grinding.

Fruit-Liquors.

233
Fermentation.

IV. *Fermentation.* The common practice is to have the liquor turned; that is, put into casks or hogsheds immediately from the press, and to fill them quite full: but it is undoubtedly more proper to leave some space empty to be filled up afterwards. No accurate experiment has been made with regard to the temperature of the air proper to be kept up in the place where the fermentation goes on. Frost is prejudicial; but when the process usually commences, that is about the middle of October, the liquor is put into airy shades, where the warmth is scarce greater than in the open atmosphere; nay, they are frequently exposed to the open air without any covering farther than a piece of tile or flat stone over the bung-hole, propped up by a wooden pin on one side to cause the rain water run off. In a complete manufactory of fruit-liquor, the fermenting room should be under the same roof with the mill-house; a continuation of the press-room, or at least opening into it, with windows or doors on every side, to give a free admission of air into it; sufficient defences against frost; fruit-lofts over it, and vaults underneath for laying up the liquors after fermentation; with small holes in the crown of the arch to admit a leathern pipe, for the purpose of conveying the liquors occasionally from the one to the other.

In making of fruit-liquors, no ferment is used as in making of beer; though, from Mr Marshall's account of the matter, it seems far from being unnecessary. Owing to this omission, the time of the commencement of the fermentation is entirely uncertain. It takes place sometimes in one, two, or three days; sometimes not till a week or month after turning; but it has been observed, that liquor which has been agitated in a carriage, though taken immediately from the press, will sometimes pass almost immediately into a state of fermentation. The continuance of the fermentation is no less uncertain than the commencement of it. Liquors, when much agitated, will go through it perhaps in one day; but when allowed to remain at rest, the fermentation commonly goes on two or three days, and sometimes five or six. The fermenting liquor, however, puts on a different appearance according to circumstances. When produced from fruits properly matured, it generally throws up a thick scum resembling that of malt liquor, and of a thickness proportioned to the species and ripeness of the fruit; the riper the fruit, the more scum being thrown up. Perry gives but little scum, and cyder will sometimes also do the same; sometimes it is intentionally prevented from doing it.

After having remained some time in the fermenting vessel, the liquor is racked or drawn off from the lees and put into fresh casks. In this part of the operation also Mr Marshall complains greatly of the little attention that is paid to the liquor. The ordinary time for racking perry is before it has done hissing, or sometimes when it begins to emit fixed air in plenty. The only intention of the operation is to free the liquor from its faeces by a cock placed at a little distance from the bottom; after which the remainder is to be

5 F

filtered

Fruit-Liquors.

filtered through a canvas or flannel bag. This filtered liquor differs from the rest in having an higher colour; having no longer any tendency to ferment, but on the contrary checking the fermentation of that which is racked off; and if it loses its brightness, it is no longer easily recovered.—A fresh fermentation usually commences after racking; and if it become violent, a fresh racking is necessary in order to check it; in consequence of which the same liquor will perhaps be racked five or six times: but if only a small degree of fermentation takes place, which is called *fretting*, it is allowed to remain in the same cask; though even here the degree of fermentation which requires racking is by no means determined. Mr Marshall informs us that the best manufacturers, however, repeat the rackings until the liquor will lie quiet, or nearly so; and if it be found impracticable to accomplish this by the ordinary method of fermentation, recourse must be had to fumigation with sulphur, which is called *stumping* the casks. For this fumigation, it is necessary to have matches made of thick linen-cloth about ten inches long, and an inch broad, thickly coated with brimstone for about eight inches of their length. The cask is then properly seasoned, and every vent except the bung-hole tightly stopped; a match kindled; lowered down into the cask, and held by the end undipped until it be well lighted and the bung be driven in; thus suspending the lighted match within the cask. Having burnt as long as the contained air will supply the fire, the match dies, the bung is raised, the remnant of the match drawn out, and the cask suffered to remain before the liquor be put into it for two or three hours, more or less according to the degree of power the sulphur ought to have. The liquor retains a smell of the sulphureous acid; but this goes off in a short time, and no bad effect is ever observed to follow.

In some places the liquor is left to ferment in open casks, where it stands till the first fermentation be pretty well over; after which the froth or yeast collected upon the surface is taken off, it being supposed that it is this yeast mixing with the clear liquor which causes it to fret after racking. The fermentation being totally ceased, and the lees subsided, the liquor is racked off into a fresh cask, and the lees filtered as above directed. Our author mentions a way of fermenting fruit-liquors in broad shallow vats, not less than five feet in diameter, and little more than two feet deep; each vat containing about two hogheads. In these the liquor remains until it has done rising, or till the fermentation has nearly ceased, when it is racked off without skimming, the critical juncture being caught before the yeast fall; the whole sinking gradually together as the liquor is drawn off. In this practice also the liquor is seldom drawn off a second time.

234
Different
kinds of
cyder, dif-
ferently
fermented.

Cyder is made of three different kinds, viz. *rough*, *sweet*, and *of a middle richness*. The first kind being usually destined for servants, is made with very little ceremony. “If it is but *zeyder* (says Mr Marshall), and has body enough to keep, no matter for the richness and flavour. The rougher it is, the further it will go, and the more acceptable custom has rendered it not only to the workmen but to their masters. A palate accustomed to sweet cyder would judge the rough cyder of the farm-houses to be a mixture of vinegar and water, with a little dissolved alum to give it rough-

ness.” The method of producing this austere liquor is to grind them in a crude under-ripe state, and subject the liquor to a full fermentation.—For the sweet liquor, make choice of the sweeter fruits: mature them fully; and check the fermentation of the liquor.—To produce liquors of a middle richness, the nature of the fruit, as well as the season in which it is matured, must be considered. The fruits to be made choice of are such as yield juices capable of affording a sufficiency both of richness and strength; though much depends upon proper management. Open vats, in our author’s opinion, are preferable to close vessels: but if casks be used at all, they ought to be very large, and not filled; nor ought they to lie upon their sides, but to be set on their ends with their heads out, and to be filled only to such an height as will produce the requisite degree of fermentation: but in whatever way the liquor be put to ferment, Mr Marshall is of opinion that the operation ought to be allowed to go on freely for the first time; though after being racked off, any second fermentation ought to be prevented as much as possible.

V. *Correcting*, provincially called *doctoring*. The Of correct-
imperfections which art attempts to supply in these li- ing or doc-
quors are, 1. Want of strength; 2. Want of richness. toring the
3. Want of flavour. 4. Want of colour and bright- liquors.

The want of strength is supplied by brandy or any other spirit in sufficient quantity to prevent the acetous fermentation. The want of richness is supplied by what are generally termed *sweets*, but prepared in a manner which our author says has never fallen under his notice. To supply the want of flavour, an infusion of hops is sometimes added, which is said to communicate an agreeable bitter, and at the same time a fragrance; whence it becomes a substitute for the juices of the rind and kernels thrown away to the pigs and poultry, or other otherwise wasted. The want of colour is sometimes supplied by elder berries, but more generally by burnt sugar, which gives the desired colour, and a degree of bitter which is very much liked. The sugar is prepared either by burning it on a salamander, and suffering it to drop, as it melts, into water; or by boiling it over the fire (in which case brown sugar is to be used), until it acquire an agreeable bitter; then pouring in boiling water in the proportion of a gallon to two lb. of sugar, and stir until the liquor become uniform. A pint of this preparation will colour a hoghead of cyder. Brightness is obtained by a mixture of the blood of bullocks or sheep; that of swine being rejected, though it does not appear to be more unfit for the purpose than either of the other two. The only thing necessary to be done here is to stir the blood well as it is drawn from the animal, to prevent the parts from separating; and it ought to be stirred “both ways, for a quarter of an hour.” The liquor, however, is not always in a proper condition for being refined with this ingredient; on which account a little of it ought frequently to be tried in a vial. A quart or less will be sufficient for a hoghead. After the blood is poured in, the liquor should be violently agitated, to mix the whole intimately together. This is done by a stick slit into four, and inserted into the bung-hole; working it briskly about in the liquor until the whole be thoroughly mixed. In about 24 hours the

Fruit-Li-
quors.

the blood will be subſided, and the liquor ought inſtantly to be racked off; as by remaining upon the blood even for two or three days, it will receive a taint not eaſily to be got rid of. It is remarkable that this refinement with the blood carries down not only the ſæces, but the colour alſo; rendering the liquor, though ever ſo highly coloured before, almoſt as limpid as water. Iſinglaſs and eggs are ſometimes made uſe of in fining cyder as well as wine.

236
Of laying
up, or caſk-
ing.

VI. The *laying up* or ſhutting up the cyder in cloſe caſks, according to Mr Marshall, is as little underſtood as any of the reſt of the parts; the bungs being commonly put in at ſome certain time, or in ſome particular month, without any regard to the ſtate the liquor itſelf is in. “The only criterion (ſays he) I have met with for judging the critical time of laying up, is when a fine white cream-like matter firſt begins to form upon the ſurface. But this may be too late; it is probably a ſymptom at leaſt of the acetous fermentation, which if it take place in any degree muſt be injurious. Yet if the caſks be bunged tight, ſome criterion is neceſſary; otherwiſe, if the vinous fermentation have not yet finally ceaſed, or ſhould recommence, the caſks will be endangered, and the liquor injured. Hence, in the practice of the moſt cautious manager whoſe practice I have had an opportunity of obſerving, the bungs are firſt driven in lightly, when the liquor is fine, and the vinous fermentation is judged to be over; and ſome time afterward, when all danger is paſt, to fill up the caſks, and drive the bungs ſecurely with a rag, and roſin them over at top. Moſt farmers are of opinion, that after the liquor is done fermenting, it ought to have ſomething to *feed upon*; that is, to prevent it from running into the acetous fermentation. For this purpoſe ſome put in parched beans, others egg-ſhells, ſome mutton-ſuet, &c. Mr Marshall does not doubt that ſomething may be uſeful; and thinks that iſinglaſs may be as proper as any thing that can be got.

237
Bottling.

VII. *Bottling*. This depends greatly on the quality of the liquors themſelves. Good cyder can ſeldom be bottled with propriety under a year old; ſometimes not till two. The proper time is when it has acquired the utmoſt degree of richneſs and flavour in the caſks; and this it will preſerve for many years in bottles. It ought to be quite fine at the time of bottling; or if not ſo naturally, ought to be fined artificially with iſinglaſs and eggs.

238
Of cyder-
kin.

THE liquor, called *cyderkin*, *purre*, or *perkin*, is made of the murk or groſs matter remaining after the cyder is preſſed out. To make this liquor, the murk is put into a large vat, with a proper quantity of boiled water, which has ſtood till it be cold again: if half the quantity of water be uſed that there was of cyder, it will be good; if the quantities be equal, the cyderkin will be ſmall. The whole is left to infuſe 48 hours, and then well preſſed: what is ſqueezed out by the preſs is immediately tunned up and ſtopped; it is fit to drink in a few days. It clarifies of itſelf, and ſerves in families inſtead of ſmall beer. It will keep, if boiled, after preſſure, with a convenient quantity of hops.

We muſt not conclude this ſection without particular notice of the liquor called *cyder wine*, which is

made from the juice of apples taken from the preſs and *boiled*, and which being kept three or four years is ſaid to reſemble Rheniſh. The method of preparing this wine, as communicated by Dr Ruſh of America, where it is much practiſed, conſiſts in evaporating in a brewing copper the freſh apple-juice till half of it be conſumed. The remainder is then immediately conveyed into a wooden cooler, and afterwards is put into a proper caſk, with an addition of yeast, and fermented in the ordinary way. The proceſs is evidently borrowed from what has long been practiſed on the recent juice of the grape, under the term of *vin cuit*, or boiled wine, not only in Italy, but alſo in the iſlands of the Archipelago, from time immemorial.

This proceſs has lately become an object of imitation in the cyder counties, and particularly in the weſt of England, where it is reported that many hundred hogs-heads of this wine have already been made; and as it is ſaid to betray no ſign of an impregnation of copper by the uſual chemical teſts, it is conſidered as perfectly wholeſome, and is accordingly drunk without apprehenſion by the common people. Others, however, ſuſpect its innocence; whence it appeared an object of no ſmall moment to determine in ſo doubtful a matter, whether or not the liquor acquires any noxious quality from the copper in which it is boiled.—With this view Dr Fothergill† made a variety of experiments; and the reſult ſeemed to afford a ſtrong preſumption that the cyder wine *does* contain a minute impregnation of copper; not very conſiderable indeed, but yet ſufficient, in the Doctor’s opinion, to put the public on their guard concerning a liquor that comes in ſo very “queſtionable a ſhape.”

It is a curious chemical fact, he obſerves, if it be really true, that acid liquors, while kept boiling in copper veſſels, acquire little or no impregnation from the metal, but preſently begin to act upon it when left to ſtand in the cold. Can this be owing to the agitation occaſioned by boiling, or the expulſion of the aerial acid? Atmospheric air powerfully corrodes copper, probably through the intervention of the aerial or rather nitrous acid, for both are now acknowledged to be preſent in the atmosphere. But the latter is doubtleſs a much ſtronger menſtrum of copper than the former.

In the preſent proceſs the liquor is properly directed to be paſſed into a wooden cooler as ſoon as the boiling is completed. But as all acids, and even common water, acquire an impregnation and unpleaſant taſte, from ſtanding in copper veſſels in the cold, why may not the acid juice of apples act in ſome degree on the copper before the boiling commences? Add to this, that brewing coppers, without far more care and attention than is generally beſtowed on them in keeping them clean, are extremely apt to contract verdegriſ, (a rank poiſon), as appears from the blue or green ſtreaks very viſible when theſe veſſels are minutely examined. Should the unfermented juice be thought incapable of acting on the copper either in a cold or boiling ſtate, yet no one will venture to deny its power of waſhing off or diſſolving verdegriſ already formed on the internal ſurface of the veſſel. Suppoſe only one-eighth part of a grain of verdegriſ to be contained in a bottle of this wine, a quantity that may elude the ordinary teſts, and that a bottle

Manures.

should be drunk daily by a person without producing any violent symptom or internal uneasiness; yet what person in his senses would knowingly chuse to hazard the experiment of determining how long he could continue even this quantity of a slow poison in his daily beverage with impunity? And yet it is to be feared the experiment is but too often unthinkingly made, not only with cyder-wine, but also with many of the foreign wines prepared by a similar process. For the grape juice, when evaporated in a copper vessel, under the denomination of *vino cotto* or boiled wine, cannot but acquire an equal if not yet stronger impregnation of the metal, than the juice of apples, seeing that verdegriis itself is manufactured merely by the application of the acid husks of grapes to plates of copper.

Independent of the danger of any metallic impregnation, the Doctor thinks it may be justly questioned how far the process of preparing boiled wines is necessary or reconcileable to reason or economy. The evaporation of the must by long boiling not only occasions an unnecessary waste of both liquor and fuel, but also dissipates certain essential principles, without which the liquor can never undergo a complete fermentation, and without a complete fermentation there can be no perfect wine. Hence the boiled wines are generally crude, heavy, and flat, liable to produce indigestion, flatulency, and diarrhoea. If the evaporation be performed hastily, the liquor contracts a burnt empyreumatic taste, as in the present instance; if slowly, the greater is the danger of a metallic impregnation. For the process may be presumed to be generally performed in a vessel of brass or copper, as few families possess any other that is sufficiently capacious. Nor can a vessel of cast-iron, though perfectly safe, be properly recommended for this purpose, as it would probably communicate a chalybeate taste and dark colour to the liquor. At all events, brass and copper vessels ought to be entirely banished from this and every other culinary process.

SECT. XI. On Manures, and the best Methods of collecting them.

WE have deferred treating on these to the last part, as they are in fact derived in more or less quantity from every operation in husbandry, though they are undoubtedly the foundation of the whole; for no method yet proposed for making a soil fertile without manure has ever been properly ascertained to be successful. The mode in which they operate has been so fully explained under the article AGRICULTURE, that nothing farther seems necessary to be added in this place. Of late, however, a new manure has been introduced into some countries, the operation of which cannot so well be explained upon the principles there laid down. This is *Gypsum*. In the eighth volume of the Annals of Agriculture we are informed, that it is commonly used as a manure in Switzerland. In the 10th volume of the same work, Sir Richard Sutton gives some account of an experiment made with it on his estate; but in such an inaccurate manner, that nothing could be determined. "The appearance in general (says he), I think, was rather against the benefit of the plaster, though not decidedly so." He tells us, that its virtues were a sub-

ject of debate in Germany. In America this substance seems to have met with more success than in any other country. In the fifth volume of Bath Papers, Mr Kirkpatrick of the Isle of Wight, who had himself visited North America, informs us, that it is much used in the United States, on account of its cheapness and efficacy; though, from what is told in the same place, we must undoubtedly be led to suppose, that its efficacy must be very great before it can be intitled to *cheapness*. In the first place, it is brought from the hills in the neighbourhood of Paris to Havre de Grace, and from thence exported to America; which of itself must occasion a considerable expence, though the plaster were originally given *gratis*. In the next place, it must be powdered in a stamping mill, and the finer it is powdered so much the better. In the third place, it must be *sown* over the ground to be manured with it. The quantity for grafs is six bushels to an acre. It ought to be sown on dry ground in a wet day; and its efficacy is said to last from seven to twelve years. It operates entirely as a top dressing.

In the 10th volume of Annals of Agriculture, we have some extracts from a treatise by Mr Powel, president of the Philadelphia Society for encouraging Agriculture, upon the subject of gypsum as a manure; of the efficacy of which he gives the following instances. 1. In October 1786, plaster of Paris was sown in a rainy day upon wheat-stubble without any previous culture. The crop of wheat had scarce been worth reaping, and no kind of grafs seed had been sown upon the ground; nevertheless, in the month of June it was covered with a thick mat of white clover, clean and even, from six to eight inches in height. A piece of ground adjoining to this white clover was also sown with gypsum, and exhibited a fine appearance of white and red clover mixed with spear-grafs. Some wet ground sown at the same time was not in the least improved.—This anecdote rests entirely on the veracity of an anonymous farmer. 2. Eight bushels of plaster of Paris spread upon two acres and an half of wheat-stubble ground, which the spring before had been sowed with about two pounds of red clover-seed to the acre for pasture, yielded five tons of hay by the middle of June. A small piece of ground of similar quality, but without any plaster, produced only one ton and an half in the same proportion.—Mr Powel concludes in favour of the effects of the plaster upon arable as well as grafs land.—Other accounts to the same purpose have been published; but it does not appear to have been tried in this country.

With regard to the other kinds of manure commonly in use in this country, their efficacy is well known; the only difficulty is to procure them in sufficient quantity.—In such lands as lie near the sea, sea-weeds offer an unlimited quantity of excellent manure. In the neighbourhood of rivers, the weeds with which they abound offer likewise an excellent manure in plenty. Oil-cake, malt-coombs, the refuse of slaughter-houses, &c. all are excellent where they can be got: but the situations which afford these are comparatively few; so that in most cases the farmer must depend much on his own ingenuity and industry for raising a sufficient quantity of dung to answer his purposes; and the methods taken for this purpose vary according to the situation of different places, or according to the fancy of the husbandman.

Manures.

242
Manures
used in
Norfolk.

In all countries where chalk, marle, or lime are to be had, they are certainly to be employed in their proper departments; but besides these, *dung*, properly so called, mixed with earth or putrid animal and vegetable substances, constitutes a principal part of the manure. In Norfolk, Mr Marshall tells us, that the *quality* of dung is attended to with greater precision than in most other districts. *Town-muck*, as it is called, is held in most estimation; and the large towns Norwich and Yarmouth supply the neighbouring country. As Yarmouth, however, is a maritime place, and otherwise in a manner surrounded by marshes, straw is of course a scarce and dear article; whence, instead of littering their horses with it, they use sand. As the bed becomes soiled or wet, fresh sand is put on, until the whole is in a manner saturated with urine and dung, when it is cleared away, and reckoned muck of such excellent quality, that it is sent for from a very great distance. With regard to other kinds of dung, that from horses fed upon hay and corn is looked upon to be the best; that of fattening cattle the next; while the dung of lean cattle, particularly of cows, is supposed to be greatly inferior, even though turnips make part of their food. The dung of cattle kept on straw alone is looked upon to be of little or no value; while the muck from trodden straw is by some thought to be better than that from the straw which is eaten by the lean-stock.—Composts of dung with earth or marle are very generally used.

243
In the Mid-
land di-
strict.

In the midland counties of England, Mr Marshall informs, the cores of horns crushed in a mill have been used as manure; though he knows not with what success. His only objection is the difficulty of reducing them to powder. Dung is extremely dear in Norfolk; half a guinea being commonly given for a wagon-load driven by five horses. Great quantities of lime and marle are found in this district.—With regard to the method of raising dung in general, perhaps the observations of Mr Marshall upon the management of the Yorkshire farmers may be equally satisfactory with any thing that has yet been published on the subject.

244
Mr Mar-
shall's direc-
tions for
raising
dung.

“The general practice (says he) is to pile the dung on the highest part of the yard; or, which is still less judicious, to let it lie scattered about on the side of a slope, as it were for the purpose of dissipating its virtues. The urine which does not mix with the dung is almost invariably led off the nearest way to the common sewer, as if it were thought a nuisance to the premises. That which mixes with the dung is of course carried to the *midden*, and assists in the general dissipation. A yard of *dung*, nine-tenths of which are straw, will discharge, even in dry weather, some of its more

fluid particles; and in rainy weather, is, notwithstanding the straw, liable to be washed away if exposed on a rising ground. But how much more liable to waste is a mixture of dung and urine, with barely a sufficiency of straw to keep them together? In dry weather the natural oozing is considerable; and in a wet season every shower of rain washes it away in quantities.—The Norfolk method of bottoming the dung-yard with mould is here indispensably necessary to common good management. There is no better manure for grass-lands than mould saturated with the oozings of a dunghill: it gets down quicker among the grass, and has generally a more visible effect than the dung itself. Under this management the arable land would have the self-same dung it now has; while the grass land would have an annual supply of riches, which now run waste in the sewers and rivulets.—But before a dung-yard can with propriety be bottomed with mould, the bottom of the yard itself ought to be properly formed. A part of it situated conveniently for carriages to come at, and low enough to receive the entire drainings of the stable, cattle-stalls, and hog sties, should be hollowed out in the manner of an artificial drinking-pool, with a rim somewhat rising, and with covered drains laid into it from the various sources of liquid manure. During the summer months, at leisure times, and embracing opportunities of back-carriage, fill the hollow nearly full with mould; such as the scowerings of ditches, the shovellings of roads, the maiden earth of lanes and waste corners, the coping of stone-quarries, &c. &c. leaving the surface somewhat dished; and within this dish set the dung-pile, carefully keeping up a rim of mould round the base of the pile higher than the adjoining surface of the yard; equally to prevent extraneous matter from finding its way into the reservoirs, and to prevent the escape of that which falls within its circuit.”

245
In the first volume of the Annals of Agriculture, Mr Young, from a theory that phlogiston is the food of plants, made several experiments upon charcoal as a manure; but the results were not sufficiently favourable to induce a trial of it in the large way. It must be remembered, that though phlogiston is very probably the true vegetable food, yet it is phlogiston volatilized, as in putrid animal and vegetable substances, not in its fixed state as in charcoal, which can have any effect. See AGRICULTURE, Part I. Sect. i. et seq.

Mr Young's
experi-
ments on
charcoal.

A very advantageous method of manuring grass-lands, when there is an opportunity, is that of overflowing them with water, which is mostly practised with low flat grounds. For an account of the best methods in use for this purpose, see the article MEADOW.

H U S

Virgilian Husbandry, a term used by authors to express that sort of husbandry, the precepts of which are so beautifully delivered in Virgil's Georgics. The husbandry in England is Virgilian in general, as is seen by the method of paring and burning the surface, of raftering or cross-ploughing, and of the care in destroying weeds, upon the same principle, and by much the same means. In those parts of England along the

H U S

southern coast, where the Romans principally inhabited, not only the practice, but the expressions, are in many respects the same with those of the ancient Romans, many of the terms used by the ploughmen being of Latin origin, and the same with those used by those people on the like occasions. And on a strict observation, more of Virgil's husbandry is at this time practised in England than in Italy itself. This change in the Italian

Husk
||
Hussites.

italian husbandry is, however, much more to the credit of that people, than the retaining the Virgilian scheme is to ours.

Tull, who has established a new method of husbandry, observes, that it is upon the whole so contradictory to this old plan, that it may be called the *anti-Virgilian husbandry*; and adds, that no practice can be worse than the Virgilian.

HUSK, the same with what botanists call the *calyx* or *cup* of a flower. See CALYX.

HUSO, in ichthyology. See ACCIPENSER.

HUSS (John). See HUSSITES.

HUSSARS, are the national cavalry of Hungary and Croatia. Their regimentals consist in a rough furred cap, adorned with a cock's feather (the officers either an eagle's or a heron's); a doublet, with a pair of breeches to which the stockings are fastened, and yellow or red boots: besides, they occasionally wear a short upper waistcoat edged with furs, and five rows of round metal buttons; and in bad weather, a cloak. Their arms are a sabre, carbine, and pistols. They are irregular troops: hence, before beginning an attack, they lay themselves so flat on the necks of their horses, that it is hardly possible to discern their force; but being come within pistol-shot of the enemy, they raise themselves with such surprising quickness, and begin the fight with such vivacity on every side, that, unless the enemy is accustomed to their method of engaging, it is very difficult for troops to preserve their order. When a retreat is necessary, their horses have so much fire, and are so indefatigable, their equipage so light, and themselves such excellent horsemen, that no other cavalry can pretend to follow them. They leap over ditches, and swim over rivers, with surprising facility. They never encamp, and consequently are not burdened with any camp-equipage, saving a kettle and a hatchet to every six men. They always lie in the woods, out-houses, or villages, in the front of the army. The emperor, queen of Hungary, and king of Prussia, have the greatest number of troops under this name in their service.

HUSSITES, in ecclesiastical history, a party of reformers, the followers of John Hufs.

John Hufs, from whom the Hussites take their name, was born in a little village in Bohemia, called *Hufs*, and lived at Prague in the highest reputation, both on account of the sanctity of his manners and the purity of his doctrine. He was distinguished by his uncommon erudition and eloquence, and performed at the same time the functions of professor of divinity in the university, and of ordinary pastor in the church of that city. He adopted the sentiments of Wickliff, and the Waldenses; and in the year 1407 began openly to oppose and preach against divers errors in doctrine, as well as corruptions in point of discipline, then reigning in the church. Hufs likewise endeavoured to the utmost of his power to withdraw the university of Prague from the jurisdiction of Gregory XII. whom the kingdom of Bohemia had hitherto acknowledged as the true and lawful head of the church. This occasioned a violent quarrel between the incensed archbishop of Prague and the zealous reformer, which the latter inflamed and augmented from day to day, by his pathetic exclamations against the court of Rome, and

the corruptions that prevailed among the sacerdotal order.

There were other circumstances that contributed to inflame the resentment of the clergy against him. He adopted the philosophical opinions of the realists, and vehemently opposed and even persecuted the nominalists, whose number and influence were considerable in the university of Prague. He also multiplied the number of his enemies in the year 1408, by procuring, through his great credit, a sentence in favour of the Bohemians, who disputed with the Germans concerning the number of suffrages which their respective nations were intitled to in all matters that were carried by election in this university. In consequence of a decree obtained in favour of the former, which restored them to their constitutional right of three suffrages, usurped by the latter, the Germans withdrew from Prague, and, in the year 1409, founded a new academy at Leipfick. This event no sooner happened, than Hufs began to inveigh with greater freedom than he had before done against the vices and corruptions of the clergy, and to recommend, in a public manner, the writings and opinions of Wickliffe, as far as they related to the papal hierarchy, the despotism of the court of Rome, and the corruption of the clergy. Hence an accusation was brought against him, in the year 1410, before the tribunal of John XXIII. by whom he was solemnly expelled from the communion of the church. Notwithstanding this sentence of excommunication, he proceeded to expose the Romish church with a fortitude and zeal that were almost universally applauded.

This eminent man, whose piety was equally sincere and fervent, though his zeal was perhaps too violent, and his prudence not always circumspect, was summoned to appear before the council of Constance. Secured, as he apprehended, from the rage of his enemies by the safe conduct granted him by the emperor Sigismund, for his journey to Constance, his residence in that place, and his return to his own country, John Hufs obeyed the order of the council, and appeared before it to demonstrate his innocence, and to prove that the charge of his having deserted the church of Rome was entirely groundless. However, his enemies so far prevailed, that by the most scandalous breach of public faith, he was cast into prison, declared a heretic because he refused to plead guilty against the dictates of his conscience, in obedience to the council, and burnt alive in 1415; a punishment which he endured with unparalleled magnanimity and resignation.

The same unhappy fate was borne by Jerome of Prague, his intimate companion, who attended the council, in order to support his persecuted friend. Jerome, indeed, was terrified into temporary submission; but he afterwards resumed his fortitude, and maintained the opinions, which he had for a while deserted through fear, in the flames in which he expired in 1416.

The disciples of Hufs adhered to their master's doctrine after his death with a zeal which broke out into an open war, that was carried on with the most savage and unparalleled barbarity. John Ziska, a Bohemian knight, in 1420, put himself at the head of the Hussites, who were now become a very considerable party,

Hussites.

Hustings party, and threw off the despotic yoke of Sigismund, who had treated their brethren in the most barbarous manner. **Hutcheson** Ziska was succeeded by Procopius, in the year 1424. The acts of barbarity that were committed on both sides were shocking and horrible beyond expression: for notwithstanding the irreconcilable opposition between the religious sentiments of the contending parties, they both agreed in this one horrible principle, that it was innocent and lawful to persecute and extirpate with fire and sword the enemies of the true religion; and such they reciprocally appeared to each other. These commotions in a great measure subsided, by the interference of the council of Basil, in the year 1433.

The Hussites, who were divided into two parties, viz. the Calixtines and Taborites, spread over all Bohemia and Hungary, and even Silesia and Poland; and there are some remains of them still subsisting in all those parts.

HUSTINGS (from the Saxon word *Hustinge*, i. e. *concilium*, or *curia*), a court held in Guild-hall before the lord-mayor and aldermen of London, and reckoned the supreme court of the city. Here deeds may be inrolled, outlawries sued out, and replevins and writs of error determined. In this court also is the election of aldermen, of the four members of parliament for the city, &c. This court is very ancient, as appears by the laws of Edward the Confessor. Some other cities have likewise had a court bearing the same name, as Winchester, York, &c.

HUSUM, a town of Denmark, in the duchy of Sleswick, and capital of a bailiwick of the same name, with a strong citadel, and a very handsome church. It is seated near the river Ow, on the German Sea; and is subject to the dukes of Holstein-Gottorp. E. Long. 9. 5. N. Lat. 54. 55.

HUTCHESON (Dr Francis), a very elegant writer and excellent philosopher, was the son of a dissenting minister in the north of Ireland, and was born on the 8th of August 1694. He early discovered a superior capacity; and having gone through a school-education, began his course of philosophy at an academy, whence he removed to the university of Glasgow, where he applied himself to all the parts of literature, in which his progress was suitable to his uncommon abilities.

He then returned to Ireland; and entering into the ministry, was just about to be settled in a small congregation of dissenters in the north of Ireland, when some gentlemen about Dublin, who knew his great abilities and virtues, invited him to take up a private academy there. He complied with the invitation, and met with much success. He had been fixed but a short time in Dublin, when his singular merits and accomplishments made him generally known; and his acquaintance was sought by men of all ranks, who had any taste for literature, or any regard for learned men. The late lord viscount Molesworth is said to have taken great pleasure in his conversation, and to have assisted him with his criticisms and observations upon his "Inquiry into the Ideas of Beauty and Virtue," before it came abroad. He received the same favour from Dr Synge, lord bishop of Elphin, with whom he also lived in great friendship. The first edition of this performance came abroad without the au-

thor's name, but the merit of it would not suffer him to be long concealed. Such was the reputation of the work, and the ideas it had raised of the author, that lord Granville, who was then lord lieutenant of Ireland, sent his private secretary to inquire at the bookseller's for the author; and when he could not learn his name, he left a letter to be conveyed to him: in consequence of which he soon became acquainted with his excellency, and was treated by him, all the time he continued in his government, with distinguished marks of familiarity and esteem.

From this time his acquaintance began to be still more courted by men of distinction either for station or literature in Ireland. Archbishop King, the author of the celebrated book *De origine mali*, held him in great esteem; and the friendship of that prelate was of great use to him in screening him from two several attempts made to prosecute him, for daring to take upon him the education of youth, without having qualified himself by subscribing the ecclesiastical canons, and obtaining a licence from the bishop. He had also a large share in the esteem of the primate Bolter, who through his influence made a donation to the university of Glasgow of a yearly fund for an exhibitioner to be bred to any of the learned professions. A few years after his "Inquiry into the Ideas of Beauty and Virtue," his "Treatise on the Passions" was published: both these works have been often reprinted; and always admired, both for the sentiment and language, even by those who have not assented to the philosophy of them, nor allowed it to have any foundation in nature. About this time he wrote some philosophical papers, accounting for laughter, in a different way from Hobbes, and more honourable to human nature: which papers were published in the collection called *Hibernicus's Letters*.

After he had taught in a private academy at Dublin for seven or eight years with great reputation and success, he was called, in the year 1729, to Scotland, to be a professor of philosophy in the university of Glasgow. Several young gentlemen came along with him from the academy, and his high reputation drew many more thither both from England and Ireland. Here he spent the remainder of his life in a manner highly honourable to himself and ornamental to the university of which he was a member. His whole time was divided between his studies and the duties of his office; except what he allotted to friendship and society. A firm constitution and a pretty uniform state of good health, except some few slight attacks of the gout, seemed to promise a longer life; yet he did not exceed the 53d year of his age. He was married, soon after his settlement in Dublin, to Mrs Mary Wilson, a gentleman's daughter in the county of Langford; by whom he left behind him one son, Francis Hutcheson, doctor of medicine. By this gentleman was published, from the original manuscript of his father, "A system of Moral Philosophy, in three books, by Francis Hutcheson, LL. D. at Glasgow, 1755," in two volumes, 4to.

HUTCHINSON (John), a philosophical writer, whose notions have made no inconsiderable noise in the world, was born in 1674. He served the duke of Somerset in the capacity of steward; and in the course of his travels from place to place employed himself in

Huxing
||
Huygens.

collecting fossils: we are told, that the large and noble collection bequeathed by Dr Woodward to the university of Cambridge was actually made by him, and even unfairly obtained from him. When he left the duke's service to indulge his studies with more freedom, the duke, then master of the horse to George I. made him his riding surveyor, a kind of sinecure place of 200l. a year with a good house in the Meuse. In 1724 he published the first part of *Moses's Principia*, in which he ridiculed Dr Woodward's Natural History of the Earth, and exploded the doctrine of gravitation established in Newton's *Principia*: in 1727, he published the second part of *Moses's Principia*, containing the principles of the Scripture Philosophy. From this time to his death, he published a volume every year or two, which, with the MSS. he left behind, were published in 1748, in 12 vols 8vo. On the Monday before his death, Dr Mead urged him to be bled; saying pleasantly, "I will soon send you to Moses," meaning to his studies: but Mr Hutchinson taking it in the literal sense, answered in a muttering tone, "I believe, Doctor, you will;" and was so displeased, that he dismissed him for another physician; but died in a few days after, August 28. 1737. Singular as his notions are, they are not without some defenders, who have obtained the appellation of *Hutchinsonians*. The reader may find a distinct and comprehensive account of the Hutchinsonian system in a book intitled, *Thoughts concerning Religion*, &c. printed at Edinburgh 1743; and in a letter to a bishop, annexed to it, first printed in 1732.

HUXING of pike, among fishermen, a particular method of catching that fish.

For this purpose, they take 30 or 40 as large bladders as can be got; blow them up, and tie them close and strong; and at the mouth of each tie a line, longer or shorter according to the depth of the water. At the end of the line is fastened an armed hook, artfully baited; and thus they are put into the water with the advantage of the wind, that they may gently move up and down the pond. When a master pike has struck himself, it affords great entertainment to see him bounce about in the water with a bladder fastened to him; at last, when they perceive him almost spent, they take him up.

HUY, a town of the Netherlands, in the bishopric of Liege, and capita. of Condras. It is advantageously seated on the river Maese, over which there is a bridge. E. Long. 10. 22. N. Lat. 52. 31.

HUYGENS (Christian), one of the greatest mathematicians and astronomers of the 17th century, was the son of Constantine Huygens, lord of Zuylichem, who had served three successive princes of Orange in the quality of secretary; and was born at the Hague, in 1629. He discovered from his infancy an extraordinary fondness for the mathematics; in a little time made a great progress in them; and perfected himself in those studies under the famous professor Schooten, at Leyden. In 1649, he went to Holstein and Denmark, in the retinue of Henry count of Nassau; and was extremely desirous of going to Sweden, in order to see Des Cartes, but the count's short stay in Denmark would not permit him. He travelled into France and England; was, in 1663, made a member of the Royal Society; and, upon his return into France, M.

N^o 160.

Colbert, being informed of his merit, settled a considerable pension upon him to engage him to fix at Paris; to which Mr Huygens consented, and staid there from the year 1666 to 1681, where he was admitted a member of the Academy of Sciences. He loved a quiet and studious manner of life, and frequently retired into the country to avoid interruption, but did not contract that moroseness which is so frequently the effect of solitude and retirement. He was the first who discovered Saturn's ring, and a third satellite belonging to that planet, which had hitherto escaped the eyes of astronomers. He discovered the means of rendering clocks exact, by applying the pendulum, and rendering all its vibrations equal by the cycloid. He brought telescopes to perfection, made many other useful discoveries, and died at the Hague in 1695. He was the author of several excellent works. The principal of these are contained in two collections; the first of which was printed at Leyden in 1682, in quarto, under the title of *Opera varia*; and the second at Amsterdam in 1728, in two volumes quarto, intitled *Opera reliqua*.

HUYSUM, the name of several Dutch painters; the most celebrated of whom was John, whose subjects were flowers, fruit, and landscapes. According to Mr Pilkington, this illustrious painter hath surpassed all who have ever painted in that style; and his works excite as much surprise by their finishing as they excite admiration by their truth. He was born at Amsterdam in 1682, and was a disciple of Justus van Huysum his father. He set out in his profession with a most commendable principle, not so much to paint for the acquisition of money as of fame; and therefore he did not aim at expedition, but at delicacy, and, if possible, to arrive at perfection in his art. Having attentively studied the pictures of Mignon, and all other artists of distinction who had painted in his own style, he tried which manner would soonest lead him to imitate the lightness and singular beauties of each flower, fruit, or plant, and then fixed on a manner peculiar to himself, which seems almost inimitable. His pictures are finished with inconceivable truth; for he painted every thing after nature; and was so singularly exact, as to watch even the hour of the day in which his model appeared in its greatest perfection. By the judicious he was accounted to paint with greater freedom than Mignon or Brueghel; with more tenderness and nature than Mario da Fiori, Michael Angelo di Campidoglio, or Segers; with more mellowness than De Heem; and greater force of colouring than Baptist. His reputation rose to such a height at last, that he fixed immoderate prices on his works; so that none but princes, or those of princely fortunes, could pretend to become purchasers. Six of his paintings were sold at a public sale in Holland for prices that were almost incredible. One of them, a flower piece, for fourteen hundred and fifty guilders; a fruit piece for a thousand and five guilders; and the smaller pictures for nine hundred. The vast sums which van Huysum received for his works, caused him to redouble his endeavours to excel; no person was admitted into his room while he was painting, not even his brothers; and his method of mixing the tints, and preserving the lustre of his colours, was an impenetrable secret, which he never would

Huysum.

Gallia,
Galliard.

caverns to be left in it. These islands are uncultivated and uninhabited since the old hermit of St Antonio died. Myrtle covers most of the surface.

GALLIA, a large country of Europe, called *Gallia* by the Greeks. The inhabitants were called *Galli*, *Celtæ*, *Celtiberi*, and *Celtoscythæ*. Ancient Gaul was divided into four different parts by the Romans, called *Gallia Belgica*, *Narbonensis*, *Aquitania*, and *Celtica*. *Gallia Belgica* was the largest province, bounded by Germany, *Gallia Narbonensis*, and the German ocean; and contained the modern country of Alsace, Lorraine, Picardy, with part of the low countries, and of Champagne, and of the isle of France. *Gallia Narbonensis*, which contained the provinces now called *Languedoc*, *Provence*, *Dauphiné*, *Savoy*, was bounded by the Alps and Pyrenean mountains, by *Aquitania*, *Belgicum*, and the Mediterranean. *Aquitania Gallia*, now called the provinces of *Poitou*, *Santonge*, *Guienne*, *Berry*, *Limosin*, *Gascogny*, *Auvergne*, &c. was situated between the *Garumna*, the Pyrenean mountains, and the ocean. *Gallia Celtica*, or *Lugdunensis*, was bounded by Belgium, *Gallia Narbonensis*, the Alps, and the ocean. It contained the country at present known by the name of *Lyonnois*, *Touraine*, *Franche Comté*, *Senenois*, *Switzerland*, and part of *Normandy*. Besides these grand divisions, there is often mention made of *Gallia Cisalpina* or *Citerior*, *Transalpina* or *Uterior*, which refers to that part of Italy which was conquered by some of the Gauls who crossed the Alps. By *Gallia Cisalpina*, the Romans understood that part of Gaul which lies in Italy, and by *Transalpina*, that which lies beyond the Alps, in regard only to the inhabitants of Rome. *Gallia Cispadana*, and *Transpadana*, is applied to a part of Italy conquered by some of the Gauls; and then it means the country on this side of the Po, or beyond the Po, with respect to Rome. By *Gallia Togata*, the Romans understood *Cisalpine Gaul*, where the Roman gowns *toga* were usually worn. *Gallia Narbonensis* was called *Braccata*, on account of the peculiar covering of the inhabitants for their thighs. The epithet of *Comata* is applied to *Gallia Celtica*, because the people suffered their hair to grow to an uncommon length. The inhabitants were great warriors, and their valour overcame the Roman armies, took the city of Rome, and invaded Greece in different ages. They spread themselves over the greatest part of the world. They were very superstitious in their religious ceremonies, and revered the sacerdotal order as if they had been gods. They long maintained a bloody war against the Romans, and Cæsar resided 10 years in their country before he could totally subdue them. See **GAUL**.

GALLIARD, or **GAGLIARDA**, a sort of dance anciently in great request; consisting of very different motions and actions, sometimes proceeding *terra à terra* or smoothly along; sometimes capering; sometimes along the room, and sometimes acrofs. The word is French, *gailliarde*, or rather Italian; and literally signifies "gay, merry, sprightly." This dance was also called *Romanesque*, because brought from Rome.

Thoinot Arbeau, in his *Orchesography*, describes it as consisting of five steps, and five positions of the feet, which the dancers performed before each other, and

whereof he gives us the score or tablature, which is of six minims, and two triple times.

GALLIARDA, in the Italian music, the name of a tune that belongs to a dance called a *galliard*. The air of it is lively in triple time.

GALLICAN, any thing belonging to France: thus the term *Gallican church* denotes the church of France, or the assembly of the clergy of that kingdom.

GALLICISM, a mode of speech peculiar to the French language, and contrary to the rules of grammar in other languages. With us it is used to denote such phrases or modes of speech in English as are formed after the French idiom.

GALLINACEUS LAPIS, a glossy substance produced by volcanic fires; the same with the *lapis obsidianus* of the ancients. A kind of it is brought from Paris, of a beautiful black, resembling the colour of a large crow in that country named *gallinago*.

GALLINÆ, in ornithology, an order of birds. See **ORNITHOLOGY**.

GALLINACIOUS, an appellation given to the birds of the order of the gallinæ.

GALLING, or **EXCORIATION**, in medicine. See **EXCORIATION**.

GALLING of a Horse's Back, a disorder occasioned by heat, and the chafing or pinching of the saddle.

In order to prevent it, some take a hind's skin well garnished with hair, and fit it neatly under the pannel of the saddle, so that the hairy side may be next the horse.

When a horse's back is galled upon a journey, take out a little of the stuffing of the pannel over the swelling, and sew a piece of soft white leather on the inside of the pannel: anoint the part with salt butter, and every evening wipe it clean, rubbing it till it grow soft, anointing it again with butter, or, for want of that, with grease: wash the swelling or hurt every evening with cold water and soap; and strew it with salt, which should be left on till the horse be saddled in the morning.

GALLINULE. See **FULICA**.

GALLIPOLI, a sea-port town of Italy, in the kingdom of Naples, and in the Terra-di-Otranto, with a bishop's see. It stands on a rocky island, joined to the continent by a bridge. From the remotest antiquity, this was a station so favourable to commerce, that every maritime power wished to secure it; and it is a reproach to government, that nothing has been done to improve its natural advantages: at present, Mr Swinburn informs us, it has neither harbour nor shelter for shipping. Charles II. demolished Gallipoli for its adherence to Frederick of Aragon. The Venetians treated it with great cruelty in the 15th century; and in 1481 it was pillaged by the Turks. To preserve it from future calamities, Charles V. repaired and strengthened its fortifications; and, since that period, it has enjoyed the benefits of peace and trade, which have rendered it the most opulent and gayest town upon the coast, though its inhabitants do not exceed 6000 in number. Consumptions and spitting of blood are rather frequent here, occasioned by the great subtilty of the air, which is ventilated from every quarter. The buildings are tolerable, and some of

Galliarde
||

Gallipoli
||
Gallois.

of the churches have good paintings. The cotton trade brings in about 30,000 ducats a-year. Good muslins, cotton stockings, and other parts of apparel, are manufactured here, and purchased by the Provençals; for Gallipoli has no direct trade with the metropolis. Silk and saffron were formerly objects of traffic; but heavy duties and oppression have caused them to be abandoned. The wine of this territory is good; but from dryness of climate, and shallowness of soil, the vintage frequently fails in quantity; and then the Gallipolitans have recourse to Sicily for a supply. Oil is the great support of the place: two-thirds of the produce of its olive plantations are exported to France, and the north of Italy; the remainder is sent to Naples, and other ports of the kingdom. Neapolitan merchants, by means of agents settled at Gallipoli, buy up the oils, from year to year, long before an olive appears upon the tree; and the price is afterwards settled by public authority. The Neapolitans sell their oil to the merchants of Leghorn; and, if faithfully served by their factors in Terra di Otranto, ought to double their capital in two years. But, to balance this advantage, they run great risks, pay exorbitant interest, and have frequent bankruptcies to guard against. E. Long. 18. 10. N. Lat. 40. 20.

GALLIPOLI, a sea-port town of Turkey in Europe, in the province of Romania, seated at the mouth of the sea of Marmura, with a good harbour, and a bishop's see. It contains about 10,000 Turks, 3500 Greeks, besides a great number of Jews. The bazar or bezeftin, the place where merchandizes are sold, is a handsome structure, with domes covered with lead. It is an open place, and has no other defence than a paltry square castle. The houses of the Greeks and Jews have doors not above three feet and an half high, to prevent the Turks riding into their houses. E. Long. 26. 59. N. Lat. 40. 30.

GALLIUM, in botany. See GALIUM.

GALLO, an island of the South Sea, near the sea-coast of Peru, in South America, which was the first place possessed by the Spaniards when they attempted the conquest of Peru; it is also the place where the bucaniers used to come for wood and water, and to relit their vessels when they were in these parts. W. Long. 88. 0. N. Lat. 2. 30.

GALLO-Græcia, a country of Asia Minor, near Bithynia and Cappadocia. It was inhabited by a colony of Gauls, who assumed the name of *Gallogræci*, because a number of Greeks had accompanied them in their emigration. See GALATIA.

GALLOIS (John), born at Paris in 1632, was an universal scholar; but chiefly noted for having been, in conjunction with M. de Sallo who formed the plan, the first publisher of the *Journal des Sçavans*. The first journal was published January 5. 1665; but these gentlemen criticised new works so rigorously, that the whole tribe of authors united and cried it down. De Sallo declined entirely after the publication of the third number: but Gallois ventured to send out a fourth, on January 4th 1666; though not without a most humble advertisement at the beginning, wherein it was declared, that the author "would not presume to criticise, but simply give an account of the books."

This, with the protection of M. Colbert, who was greatly taken with the work, gradually reconciled the public to it: and thus began literary journals, which have been continued from that time to this, under various titles, and by various writers. Gallois continued his journal to the year 1674, when more important occupations obliged him to turn it over to other hands. M. Colbert had taken him into his house to teach him Latin; and when he lost his patron in 1683, he was first made librarian to the king, and then Greek professor in the royal college. He died in 1707.

GALLON, a measure of capacity both for dry and liquid things, containing four quarts. But these quarts, and consequently the gallon itself, are different, according to the quality of the thing measured: For instance, the wine gallon contains 231 cubic inches, and holds eight pounds averdupois of pure water; the beer and ale gallon contains 281 solid inches, and holds ten pounds three ounces and a quarter averdupois of water; and the gallon for corn, meal, &c. 272½ cubic inches, and holds nine pounds thirteen ounces of pure water.

GALLOP, in the manege, is the swiftest natural pace of a horse, performed by reaches or leaps; the two fore-feet being raised almost at the same time; and when these are in the air, and just ready to touch the ground again, the two hind-feet are lifted almost at once. The word is borrowed from the barbarous Latin *calupare*, or *calpare*, "to run." Some derive it from *caballicare*; others from the Greek *καλπάζειν*, or *καλπάζειν*, to spur a horse.

GALLOPER, in artillery, is the name of a carriage which serves for a pound and a half gun. This carriage has shafts so as to be drawn without a limber, and is thought by some to be more convenient and preferable to other field carriages; and it may likewise serve for our light three and six pounders.

GALLOWAY, a county of Scotland, which gives the title of Earl to a branch of the noble family of Stuart. It is divided into two districts; the western, called *Upper Galloway*, being the same with Wigtonshire; and the eastern, or stewartry of Kirkcudbright, called *Lower Galloway*. See KIRKCUDBRIGHT and WIGTONSHIRE.

Mull of GALLOWAY, the south cape or promontory of all Scotland, in the county of Galloway, on the Irish sea.

GALLOWAYS is the name of a peculiar sort of horses, so called from the county of Galloway in Scotland, where they are bred. Tradition reports, that this kind of horses sprung from some Spanish Gallions, which swam on shore from some of the ships of the famous Spanish armada, wrecked on the coast; and coupling with the mares of the country, furnished the kingdom with their posterity. They were much esteemed, and of a middling size, strong, active, nervous, and hardy.

GALLOWS, an instrument of punishment, whereon persons convicted capitally of felony, &c. are executed by hanging.

Among our ancestors it was called *furca*, "fork;" a name by which it is still denominated abroad, particularly in France and Italy. In this latter country, the

Gallon
||
Gallows.

Huyfum. would disclose. Yet this conduct is certainly not to his honour, but rather an argument of a low mind, fearful of being equalled or surpassed. From the same principle, he would never take any disciples, except one lady, named Haverman; and he grew envious and jealous even of her merit. By several domestic disquiets his temper became changed; he grew morose, fretful, and apt to withdraw himself from society. He had many enviers of his fame, which has ever been the severe lot of the most deserving in all professions; but he continued to work, and his reputation never diminished. It is universally agreed that he has excelled all who have painted fruit and flowers before him, by the confessed superiority of his touch, by the delicacy of his pencil, and by an amazing manner of finishing; nor does it appear probable that any future artist will become his competitor. The care which he took to purify his oils and prepare his colours, and the various experiments he made to discover the most lustrous and durable, are instances of extraordinary care and industry as well as capacity. From having observed some of his works that were perfectly finished, some only half finished, and others only begun, the principles by which he conducted himself may perhaps be discoverable. His cloths were prepared with the greatest care, and primed with white, with all possible purity, to prevent his colours from being obscured, as he laid them on very lightly. He glazed all other colours except the clear and transparent, not omitting even the white ones, till he found the exact tone of the colour; and over that he finished the forms, the lights, the shadows, and the reflections, which are all executed with precision and warmth, without dryness or negligence. The greatest truth, united with the greatest brilliancy, and a velvet softness on the surface of his objects, are visible in every part of his compositions; and as to his touch, it looks like the pencil of nature. Whenever he represented flowers placed in vases, he always painted those vases after some elegant model, and the bas-relief is as exquisitely finished as any of the other parts. Through the whole he shows a delicate composition, a fine harmony, and a most happy effect of light and shadow. Those pictures which he painted on a clear ground are preferred to others of his hand, as having greater lustre, and as they demanded more care and exactness in the finishing; yet there are some on a darkish ground, in which appears rather more force and harmony. It is observed of him, that in the grouping of his flowers, he generally designed those which were brightest in the centre, and gradually decreased the force of his colour from the centre to the extremities. The birds nests and their eggs, the feathers, insects, and drops of dew, are expressed with the utmost truth, so as even to deceive the spectator. And yet, after all this merited and just praise, it cannot but be confessed, that sometimes his fruits appear like wax or ivory, without that peculiar softness and warmth, which is constantly observable in nature. Beside his merit as a flower painter, he also painted landscapes with great applause. They are well composed; and although he had never seen Rome, he adorned his scenes with the noble remains of ancient magnificence which are in that city. His pictures in that style are well coloured, and every tree is distinguished by a touch that is proper for the leafing. The grounds

are well broken, and disposed with taste and judgment; the figures are designed in the manner of Laireffe, highly finished, and touched with a great deal of spirit; and through the whole composition, the scene represents Italy, in the trees, the clouds, and the skies. He died in 1749, aged 67.

HUZZOOR, a Hindostan word signifying *The presence*; applied, by way of eminence, to the Mogul's court. According to polite usage, it is now applied to the presence of every Nabob or great man.

Huzzoor Neves; the secretary who resides at court, and keeps copies of all *firmans*, records, or letters.

HYACINTH, in natural history, a genus of pellucid gems, whose colour is red with an admixture of yellow.

The hyacinth, though less striking to the eye than any other red gem, is not without its beauty in the finest specimens. It is found of various sizes, from that of a pin's head to the third of an inch in diameter. They are harder than quartz-crystals; transparent, and formed into prisms pointed at both ends. These points are always regular with regard to the number of facets; being four on each facet, but the latter seldom: the sides of the main body are also very uncertain, in regard both to their number and shape; being found of four, five, six, seven, and sometimes of eight sides; sometimes being so compressed as almost to resemble the face of a spherical faceted garnet. Sometimes they are of a dodecaedral form like the garnet, but with more obtuse angles. The specific gravity of the hyacinth, according to Dutans, is 2.631; but Rome de L'isle says that Brisson found it to be 3.6873; and the European hyacinths to be 3.760.

The hyacinth, as well as all other gems, is divided into oriental and occidental; the former being very hard and brilliant, so that they are frequently ranked among the topazes; but when soft, they are supposed to belong to the garnet kind, as mentioned under that article. The hyacinths, however, may generally be distinguished from the garnets by losing their colour in the fire, becoming white, and not melting. There is a kind of a yellow-brown hyacinth, resembling the colour of honey, which is distinguished from the rest by the remarkable property of not being electrical, and being likewise inferior in hardness.

Our jewellers allow all those gems to be hyacinths or jacinths that are of a due hardness with the mixed colour above mentioned; and as they are of very different beauty and value in their several degrees and mixture of colours, they divide them into four kinds; three of which they call *hyacinths*, but the fourth, very improperly, a *ruby*. 1. When the stone is in its most perfect state, and of a pure and bright flame-colour, neither the red nor the yellow prevailing, in this state they call it *hyacintha la belle*. 2. When it has an overproportion of the red, and that of a duskier colour than the fine high red in the former, and the yellow that appears in a faint degree in it is not a fine, bright, and clear, but a dusky brownish yellow, then they call it the *saffron hyacinth*. 3. Such stones as are of a dead whitish yellow, with a very small proportion of red in them, they call *amber-hyacinths*. And, 4. When the stone is of a fine deep red, blended with a dusky and very deep yellow, they call it a *rubacelle*.

Hyacinthus But though the over proportion of a strong red in this gem has made people refer it to the class of rubies, its evident mixture of yellow shows that it truly belongs to the hyacinth.

Hyacinthia

The hyacinth la belle is found both in the East and West Indies. The oriental is the harder, but the American is often equal to it in colour. The rubacelle is found only in the East Indies, and is generally brought over among the rubies; but it is of little value: the other varieties are found in Silesia and Bohemia.

HYACINTHUS, **HYACINTH**, in botany: A genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 10th order, *Coronaria*. The corolla is campanulated, and there are three melliferous pores at the top of the germen. There are six species; of which the most remarkable is the orientalis, or eastern hyacinth. Of this there are a great number of varieties, amounting to some hundreds, each of which differs from the rest in some respect or other. This plant hath a large, purplish, bulbous root, sending up several narrow erect leaves eight or ten inches long; the flower stalk is upright, robust, and succulent, from 10 to 15 inches in height; adorned upward with many large funnel or bell-shaped flowers, swelling at the base, and cut half way into six parts; collected into a large pyramidal spike of different colours in the varieties; flowering in April or May.

These plants are cultivated with the greatest success in Holland, from whence great numbers are annually imported into Britain. Each variety is by the florists distinguished either by the name of the place where first raised, or the person who raised them, or the names of illustrious personages, as of kings, generals, poets, and celebrated ancient historians, gods, goddesses, &c. They are sold by all the seed-dealers. The prices are from three pence per root to five or ten pounds or more; and some varieties are in such high esteem among the florists, that 20*l.* or 30*l.* will be given for a single bulb. They are hardy, and will prosper any where, though the fine kinds require a little shelter during the winter. They may be propagated either by seeds or off-sets from the roots.

The properties of a good oriental hyacinth are, a stem perfectly upright, of moderate length, and so strong and well-proportioned that it will sustain the weight of the florets without bending: the florets should be large, swelling below, expanded above, and numerous, 10 or 15 at least, but are often 20 or 30 in number; and should be placed equally round the stem, the pedicles on which they grow longer below than above, diminishing gradually in length upward in such a manner as to represent a pyramid, and each pedicle sufficiently strong to support the florets without drooping. The curious in these plants are careful never to plant the fine sorts two years together in the same bed of earth; for, by planting them every year in a fresh bed, the beauty of the flowers is greatly improved.

HYACINTHIA, in antiquity, feasts held at Sparta, in honour of Apollo, and in commemoration of his favourite Hyacinth.

This Hyacinth was the son of Amyclas king of Sparta, and was beloved both by Apollo and Zephy-

rus. The youth showing most inclination to the former, his rival grew jealous; and, to be revenged, one day as Apollo was playing at the discus, i. e. quoits, with Hyacinth, Zephyrus turned the direction of a quoit which Apollo had pitched full upon the head of the unhappy Hyacinth, who fell down dead. Apollo then transformed him into a flower of the same name; and as a farther token of respect, they say, commanded this feast. The Hyacinthia lasted three days; the first and third whereof were employed in bewailing the death of Hyacinth, and the second in feasting and rejoicing.

HYADES, in astronomy, are seven stars in the bull's head, famous among the poets for the bringing of rain. Whence their name *Tades*, from the Greek *τὰς* "to rain." The principal of them is in the left eye, by the Arabs called *aldebaran*.

The poets feign them the daughters of Atlas and Pleone. Their brother Hyas being torn to pieces by a lioness, they wept his death with such vehemence, that the gods, in compassion to them, translated them into heaven, and placed them in the bull's forehead, where they continue to weep; this constellation being supposed to presage rain. Others represent the Hyades as Bacchus's nurses; and the same with the Dodonides, who fearing the resentment of Juno, and flying from the cruelty of king Lycurgus, were translated by Jupiter into heaven.

HYÆNA, in zoology, see **CANIS**.

HYÆNIUS LAPIS, in natural history, the name of a stone said to be found in the eyes of the hyæna. Pliny tells us, that those creatures were in old times hunted and destroyed for the sake of these stones, and that it was supposed they gave a man the gift of prophecy by being put under his tongue.

HYBERNACULUM, in botany, **WINTER-QUARTERS**; defined by Linnæus to be part of the plant which defends the embryo herb from injuries during the severities of the winter. See **BULB** and **GEMMA**.

HYBLA (anc. geog.), or **MEGARA**; which last name it took from the Megareans, who led thither a colony; called also *Hybla Parva*, and *Galeotis*. In Strabo's time Megara was extinct, but the name *Hybla* remained on account of its excellent honey named from it. It was situated on the east coast of Sicily, between Syracuse and the Leontines. *Galeota*, and *Megarensetes*, the names of the people, who were of a prophetic spirit, being the descendants of Galeus the son of Apollo. *Hybla* the epithet.—The *Hyblai colles*, small eminences at the springs of the Alabus near this place, were famous for their variety of flowers, especially thyme; the honey gathered from which was by the ancients reckoned the best in the world, excepting that of Hymettus in Attica. By the moderns it was called *Mel Passi*, for the same reason, namely, on account of its excellent honey, and extraordinary fertility, till it was overwhelmed by the lava of Ætna; and having then become totally barren, its name was changed to *Mal Passi*. In a second eruption, by a shower of ashes from the mountain, it soon reassumed its ancient beauty and fertility, and for many years was called *Bel Passi*; and last of all, in the year 1669, it was again laid under an ocean of fire, and reduced to the most wretched sterility; since which time it is again known by

Hyades

Hybla

Hybla
||
Hyde.

by the appellation of *Mal Passi*. However, the lava in its course over this beautiful country has left several little islands or hillocks, just sufficient to show what it formerly was. These make a singular appearance in all the bloom of the most luxuriant vegetation, surrounded and rendered almost inaccessible by large fields of black and rugged lava.

HYBLA-Major, (anc. geog.), was situated in the tract lying between mount *Ætna* and the river *Symethus*. In Pausanias's time desolate.

HYBLA-Minor, or *Heraa*, (anc. geog.), an inland town of Sicily, situated between the rivers *Oanus* and *Herminius*; now *RAGUSA*.

HYBRIDA PLANTA, a monstrous production of two different species of plants, analogous to a mule among animals. The seeds of hybrid plants will not propagate.

HYBRISTICA, (of *vice injury*), in antiquity, a solemn feast held among the Greeks, with sacrifices and other ceremonies; at which the men attended in the apparel of women, and the women in that of men, to do honour to *Venus* in quality either of a god or a goddess, or both. Or, according to the account given by others, the *hybristica* was a feast celebrated at *Argos*, wherein the women, being dressed like men, insulted their husbands, and treated them with all marks of superiority, in memory of the *Argian* dames having anciently defended their country with singular courage against *Cleomenes* and *Demaratus*.

Plutarch speaks of this feast in his treatise of the great actions of women. The name, he observes, signifies infamy; which is well accommodated to the occasion, wherein the women strutted about in men's cloaths, while the men were obliged to dangle in petticoats.

HYDATIDES, in medicine, little transparent vesicles or bladders full of water, sometimes found solitary, and sometimes in clusters, upon the liver and various other parts, especially in hydropical cases.

HYDATOSCOPIA, called also **HYDROMANCY**, a kind of divination or method of foretelling future events by water.

HYDE (Edward), earl of Clarendon, and lord high chancellor of England, was descended from an ancient family in Cheshire, and born at Dinton near Hindon, in Wiltshire, in 1608. He was entered of Magdalen-hall, Oxford, where, in 1625, he took the degree of *A. B.* and afterwards studied the law in the Middle-Temple. In the parliament which begun at Westminster April 10. 1640, he served for Wotton-Basset in Wiltshire. But that parliament being soon after dissolved, he was chosen for Saltash in Cornwall in the long parliament. His abilities were much taken notice of, and he was employed in several committees to examine into divers grievances; but at last being dissatisfied with the proceedings in the parliament, he retired to the king, and was made chancellor of the exchequer, a privy-counsellor, and knight. Upon the declining of the king's cause, he went to France, where, after the death of king Charles I. he was sworn of the privy council to Charles II. In 1649, he and the lord Cottington were sent ambassadors extraordinary into Spain, and in 1657 he was constituted lord high chancellor of England. The year before the restoration, the duke of York fell in love with Mrs

Hyde.

Anne Hyde, the lord chancellor's eldest daughter, but carefully concealed the amour both from the king and chancellor. As it was by a promise of marriage, however, that he had gained upon her, he was afterwards induced to fulfil his engagement, and the ceremony was performed after the restoration. Upon the restoration, her father was chosen chancellor of the university of Oxford; and soon after created baron Hindon, in Wiltshire, viscount Cornbury in Oxfordshire, and earl of Clarendon in Wiltshire; and on the death of Henry lord Falkland, was made lord lieutenant of Oxfordshire. He took care neither to load the king's prerogative, nor encroach upon the liberties of the people; and therefore would not set aside the petition of right, nor endeavour to raise the star-chamber or high-commission courts again: nor did he attempt to repeal the bill for triennial parliaments; and when he might have obtained two millions for a standing revenue, he asked but one million two hundred thousand pounds *per annum*, which he thought would still put the king upon the necessity of having recourse to his parliament. In this just conduct he is said to have been influenced by the following incident, which happened some years before. When he first began to grow eminent in the law he went down to visit his father in Wiltshire; who, one day as they were walking in the fields together, observed to him, that men of his profession were apt to stretch the prerogative too far, and to injure liberty; but charged him, if ever he came to any eminence in his profession, never to sacrifice the laws and liberty of his country to his own interest or the will of his prince: he repeated his advice twice; and immediately falling into a fit of an apoplexy, died in a few hours: and this circumstance had a lasting influence upon him. In 1662, he opposed a proposal for the king's marriage with the infant of Portugal, and the sale of Dunkirk: however, the following year, articles of high treason were exhibited against him by the earl of Bristol; but they were rejected by the house of lords. In 1664, he opposed the war with Holland. In August 1667, he was removed from his post of lord chancellor; and in November following impeached of high treason and other crimes and misdemeanors by the house of commons: upon which he retired into France, when a bill was passed for banishing him from the king's dominions. See *BRITAIN*, n° 211, 217. He resided at Rouen in Normandy; and dying there in 1674, his body was brought to England and interred in Westminster-abbey. He wrote, 1. A history of the rebellion, 3 vols folio, and 6 vols octavo; a second part of which was lately bequeathed to the public by his lordship's descendant the late lord Hyde and Cornbury. 2. A letter to the duke of York, and another to the duchess of York, upon occasion of their embracing the Romish religion. 3. An answer to Hobbes's *Leviathan*. 4. A history of the rebellion and civil wars in Ireland, octavo; and some other works.

The reverend Mr Granger, in his *Biographical History of England*, observes, that "the virtue of the earl of Clarendon was of too stubborn a nature for the age of Charles II. Could he have been content (says he) to have enslaved millions, he might have been more a monarch than an unprincipled king. But he did not only look upon himself as the guardian of the laws and liberties of his country, but had also a pride

Hyde.

in his nature that was above vice; and chose rather to be a victim himself, than to sacrifice his integrity. He had only one part to act, which was that of an honest man. His enemies allowed themselves a much greater latitude; they loaded him with calumnies, blamed him even for their own errors and misconduct, and helped to ruin him by such buffooneries as he despised. He was a much greater, perhaps a much happier, man, alone and in exile, than Charles the Second upon his throne."

And the following character of this nobleman is given by Mr Walpole. "Sir Edward Hyde (says he), who opposed an arbitrary court, and embraced the party of an afflicted one, must be allowed to have acted conscientiously. A better proof was his behaviour on the restoration, when the torrent of an infatuated nation intreated the king and his minister to be absolute. Had Clarendon fought nothing but power, his power had never ceased. A corrupted court and a blinded populace were less the causes of the chancellor's fall, than an ungrateful king, who could not pardon his lordship's having refused to accept for him the slavery of his country. Like justice herself, he held the balance between the necessary power of the supreme magistrate and the interests of the people. This never-dying obligation his contemporaries were taught to overlook and clamour against, till they removed the only man, who, if he could, would have corrected his master's evil government. Almost every virtue of a minister made his character venerable. As an historian, he seems more exceptionable. His majesty and eloquence, his power of painting characters, his knowledge of his subject, rank him in the first class of writers; yet he has both great and little faults. Of the latter, his stories of ghosts and omens are not to be defended. His capital fault is his whole work being a laboured justification of king Charles. If he relates faults, some palliating epithet always slides in; and he has the art of breaking his darkest shades with gleams of light that take off all impression of horror. One may pronounce on my lord Clarendon, in his double capacity of statesman and historian, that he acted for liberty, but wrote for prerogative."

HYDE (Dr Thomas), professor of Arabic at Oxford, and one of the most learned writers of the 17th century, was born in 1636; and studied first at Cambridge, and afterwards at Oxford. Before he was 18 years of age, he was sent from Cambridge to London to assist Mr Brian Walton in the great work of the Polyglot Bible; and about that period undertook to transcribe the Persian Pentateuch out of the Hebrew characters, which archbishop Usher, who well knew the difficulty of the undertaking, pronounced to be an impossible task to a native Persian. After he had happily succeeded in this, he assisted in correcting several parts of Mr Walton's work, for which he was perfectly qualified. He was made archdeacon of Gloucester, canon of Christ-church, head keeper of the Bodleian library, and professor both of Hebrew and Arabic, in the university of Oxford. He was interpreter and secretary of the Oriental languages, during the reigns of Charles II. James II. and William III.; and was perfectly qualified to fill this post, as he could converse in the languages which he understood. There never was an Englishman in his situation of life who made so

great a progress; but his mind was so engrossed by his beloved studies, that he is said to have been but ill qualified to appear to any advantage in common conversation. Of all his learned works (the very catalogue of which, as observed by Anth. Wood, is a curiosity), his *Religio Veterum Persarum* is the most celebrated. Dr Gregory Sharpe, the late learned and ingenious master of the Temple, has collected several of his pieces formerly printed, and republished them, with some additional dissertations, and his life prefixed, in two elegant volumes quarto. This great man died on the 18th of February, 1702. Among his other works are, 1. A Latin translation of Ulug Beig's observations on the longitude and latitude of the fixed stars; and, 2. A catalogue of the printed books in the Bodleian library.

HYDNUM, in botany: A genus of the natural order of fungi, belonging to the cryptogamia class of plants. The fungus is echinated or prickly on the under side. One of the species, named the *Imbricatum*, is a native of Britain, and is found in woods. It hath a convex hat, tiled, standing on a smooth pillar, of a pale flesh-colour, with white prickles. It is eaten in Italy, and is said to be of a very delicate taste.

HYDRA, in fabulous history, a serpent in the marsh of Lerna, in Peloponnesus, represented by the poets with many heads, one of which being cut off, another immediately succeeded in its place, unless the wound was instantly cauterized. Hercules attacked this monster; and having caused Iolaus to hew down wood for flaming brands, as he cut off the heads he applied the brands to the wounds, by which means he destroyed the Hydra.

This hydra with many heads is said to have been only a multitude of serpents, which infested the marshes of Lerna near Mycene, and which seemed to multiply as they were destroyed. Hercules, with the assistance of his companions, cleared the country of them, by burning the reeds in which they lodged.

HYDRA, in astronomy, a southern constellation, consisting of a number of stars, imagined to represent a water serpent. The stars in Hydra, in Ptolemy's catalogue, are twenty-seven; in Tycho's, nineteen; in Hevelius's, thirty-one.

HYDRA, in zoology; a genus of the order of zoophyta, belonging to the class of vermes. There are several species, known by the general name of polypes. See POLYPE; and ANIMALCULE, n° 24. & seq.

HYDRAGOGUES, among physicians, remedies which evacuate a large quantity of water in dropsies. The word is formed of *υδωρ* water, and *αγειν* to draw or lead; but the application of the term proceeds upon a mistaken supposition, that every purgative had some particular humour which it would evacuate, and which could not be evacuated by any other. It is now, however, discovered, that all strong purgatives will prove *hydragogues*, if given in large quantity, or in weak constitutions. The principal medicines recommended as *hydragogues*, are the juice of elder, the root of iris, foldanella, mechoacan, jalap, &c.

HYDRANGEA, in botany: A genus of the digynia order, belonging to the decandria class of plants; and in the natural method ranking under the 13th order, *Succulenta*. The capsule is bilocular, birostrated,

Hydnum

Hydrangea

Hydrastis and cut round, or parting horizontally. There is but one species, *viz.* the *arborescens*, a native of North America, from whence it hath lately been brought to Europe, and is preserved in gardens, more for the sake of variety than beauty. It rises about three feet high; and hath many soft pithy stalks, garnished with two oblong heart-shaped leaves placed opposite. The flowers are produced at the top of the stalks in a corymbus. They are white, composed of five petals with ten stamina surrounding the style. It is easily propagated by parting the roots; the best time for which is the end of October. The plants thrive best in a moist soil, and require to be sheltered from severe frosts.

HYDRASTIS, in botany: A genus of the polygamia order, belonging to the polyandria class of plants; and in the natural method ranking with those of which the order is doubtful. There is neither calyx nor nectarium; there are three petals; and the berry is composed of monospermous acini.

HYDRARGYRUM, a name given to mercury, or quicksilver. The word is formed of *υδωρ* *aqua*, "water," and *αργυρος*, *argentum*, "silver;" *q. d.* *water of silver*, on account of its resembling liquid or melted silver.

HYDRAULICS, the science of the motion of fluids, and the construction of all kinds of instruments and machines relating thereto. See **HYDROSTATICS**, sect. iv.

HYDRENTEROCELE, in surgery, a species of hernia, wherein the intestines descend into the scrotum, together with a quantity of water.

HYDROCELE, in surgery, denotes any hernia arising from water; but is particularly used for such a one of the scrotum, which sometimes grows to the size of one's head, without pain, but exceedingly troublesome to the patient. See **SURGERY**.

HYDROCEPHALUS, a preternatural distension of the head to an uncommon size by a stagnation and extravasation of the lymph; which, when collected in the inside of the cranium, is then termed *internal*; as that collected on the outside is termed *external*. See (the *Index* subjoined to) **MEDICINE**.

HYDROCHARIS, the **LITTLE WATER-LILY**: A genus of the annandria order, belonging to the diœcia class of plants; and in the natural method ranking under the first order, *Palma*. The spathe of the male is diphyllous; the calyx trifid; the corolla tripetalous; the three interior filaments styliiferous. The female calyx trifid; the corolla tripetalous; the styles six; the capsule has six cells, and is polyspermous inferior. There is only one species, a native of Britain, growing in flow streams and wet ditches. It hath kidney-shaped leaves, thick, smooth, and of a brownish green colour, with white blossoms. There is a variety with double flowers of a very sweet smell.

HYDROCOTYLE, **WATER-NAVELWORT**: A genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 45th order, *Umbellata*. The umbel is simple; the involucre tetraphyllous; the petals entire; the seeds are half round and compressed. There are several species, none of which are ever cultivated in gardens. One of them, a native of Britain, growing in marshy grounds, is supposed by the farmers to occasion

the rot in sheep. The leaves have central leaf-stalks, with about five flowers in a bundle; the petals are of a reddish white.

HYDROGRAPHY, the art of measuring and describing the sea, rivers, canals, lakes, &c.—With regard to the sea, it gives an account of its tides, counter-tides, soundings, bays, gulphs, creeks, &c.; as also of the rocks, shelves, sands, shallows, promontories, harbours; the distance and bearing of one port from another; with every thing that is remarkable, whether out at sea or on the coast.

HYDROLEA, in botany: A genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking with those of which the order is doubtful. The calyx is pentaphyllous; the corolla rotaceous; the filaments at the base are cordate; the capsule is bilocular and bivalved.

HYDROMANCY, a method of divination by water, practised by the ancients. See **DIVINATION**, n^o 7.

HYDROMEL, honey diluted in nearly an equal weight of water. When this liquor has not fermented, it is called *simple hydromel*; and when it has undergone the spirituous fermentation, it is called the *vinous hydromel* or *mead*.

Honey, like all saccharine substances, vegetable or animal, is susceptible of fermentation in general, and particularly of the spirituous fermentation. To induce this fermentation, nothing is necessary but to dilute it sufficiently in water, and to leave this liquor exposed to a convenient degree of heat. To make good vinous hydromel or mead, the whitest, purest, and best-tasted honey must be chosen; and this must be put into a kettle with more than its weight of water: a part of this liquor must be evaporated by boiling, and the liquor scummed, till its consistence is such that a fresh egg shall be supported upon its surface without sinking more than half its thickness into the liquor; then the liquor is to be strained and poured through a funnel into a barrel: this barrel, which ought to be nearly full, must be exposed to a heat as equable as is possible, from 20 to 27 or 28 degrees of Mr Reaumur's thermometer, taking care that the bung-hole be slightly covered, but not closed. The phenomena of the spirituous fermentation will appear in this liquor, and will subsist during two or three months, according to the degree of heat; after which they will diminish and cease. During this fermentation, the barrel must be filled up occasionally with more of the same kind of liquor of honey, some of which ought to be kept apart on purpose to replace the liquor which flows out of the barrel in froth. When the fermentation ceases, and the liquor has become very vinous, the barrel is then to be put in a cellar and well closed. A year afterwards the mead will be fit to be put into bottles.

The vinous hydromel or mead is an agreeable kind of wine: nevertheless it retains long a taste of honey, which is displeasing to some persons; but this taste it is said to lose entirely by being kept a very long time.

The spirituous fermentation of honey, as also that of sugar, and of the most of vinous liquors, when it is very saccharine, is generally more difficultly effected, requires more heat, and continues longer than that of ordinary wines made from the juice of grapes; and these vinous liquors always preserve a saccharine taste, which

||
Hydromel.

Hydrom-
eter.

which shows that a part only of them is become spiri-
tuous.

HYDROMETER, an instrument to measure the gravity, density, velocity, force, &c. of water and other fluids. See **HYDROSTATICS**, n° 13.

Though this instrument is incapable of determining the specific gravity of liquors with perfect accuracy, yet in the way of public business it has undoubtedly the advantage of every other, on account of the ease and expedition with which it can be used; and for this reason it has been adopted by government, in order to determine the strength of spirituous liquors.

Phil. Trans.
vol. 80.
p. 342.

Dr Blagden, who was lately employed to make experiments on this subject, is of opinion, that glass is the most proper material for the construction of an hydrometer. Its sensibility depends on the size of its stem. In the old areometers the stem was made so large, that the volume of water displaced between its least and greatest immersions was equal to the whole difference of specific gravity between water and alcohol, or perhaps more; whence its scale of divisions must be very small, and could not give the specific gravity with much accuracy. On this account weights were introduced, by means of which the stem could be made smaller; each weight affording a new commencement of its scale; so that the size of the divisions on a given length was doubled, tripled, &c. as one or more weights were employed, the diameter of the stem being lessened in the subduplicate proportion of the increased length of the divisions. This method, however, in our author's opinion, has been carried to excess; and the following is recommended as a proper mean betwixt these extremes, to determine the specific gravity of spirituous liquors to three places of decimals.

In this method the weight of water is supposed to be unity, or 1 with any number of cyphers annexed: "the whole compass of numbers, therefore, from rectified spirit to water, at 60 degrees of heat, would be the difference between 825, the weight of rectified spirit, and 1000 the weight of water, which is 175. To make allowance for the lightest spirit and heaviest water, however, at all the common temperatures, the difference may be supposed 220. The stem might show every twenty of these divisions, and thus ten weights would be sufficient for the whole. Hence the inconvenience of shifting the weights, which has always been complained of, would in a great measure be avoided: as people versant in that business would seldom err so far as to the whole amount of the difference previous to making any trial. Hence also the stem may be made small enough, and the scale graduated so nicely as to make the instrument sufficiently accurate.

According to this arrangement, it would be proper to have the weights adapted to the hydrometer marked with the different specific gravities which they are intended to indicate; Zero on the top of the stem without a weight being supposed to mean 800, and 20 at the bottom to signify 820, which number the first weight would carry; the successive weights being marked, 840, 860, &c.; and the division on the stem cut by the fluid under trial, would be a number always to be added to that on the weight; the sum of the two showing the true specific gravity. The weights should undoubtedly be made to apply on the top of the

stem, so as never to come in contact with the liquor; and in using the hydrometer, its stem should always be pressed down lower than the point at which it will ultimately rest, that by being wetted it may occasion no resistance to the fluid. The instrument itself should be of as regular a shape and with as few inequalities as possible, that all impediments to its motions may be avoided.

HYDROMPHALUS, in medicine and surgery, a tumor in the navel, arising from a collection of water.

HYDROPHANES, **OCULUS MUNDI**, or *Lapis Mutabilis*, a kind of precious stone highly esteemed among the ancients, but little known to the moderns till Mr Boyle made his observations upon it. Its specific gravity is about 2.048; its colour of an opaque whitish brown; it is not soluble in acids nor affected by alkalies, but is easily cut and polished. Sometimes it gives fire with steel, sometimes not. It is infusible *per se*; but when urged by a blow-pipe, changes to a brownish brittle substance. It is found in beds over the opals in Hungary, Silesia, and Saxony, and over the chalcidies and agates in Iceland. These stones in general are either of a yellowish green, milky grey, or of a yellow like that of amber.

The most remarkable property of this stone is, that it becomes transparent by mere infusion in any aqueous fluid; but gradually resumes its opacity when dry. There are three of these stones in the British museum at London; the largest of them about the size of a cherry stone, but of an oval form. It is opaque and coloured like a common yellow pea; it may be scratched, though not without difficulty, by a common knife, notwithstanding which it seems to leave a mark upon glass. It does not ferment with nitrous acid. When it has lain some hours in water, it becomes transparent, and of a yellow amber colour. The change begins soon after the immersion, and at one end in form of a little spot; but in a small one of the same kind, the transparency begins round the edges. By degrees the spot increases, until the whole stone becomes uniformly clear throughout: when out of the water it loses its transparency, first at one end, and then gradually over the remainder, until the whole has become opaque; which change happens in less time than it takes to become transparent. This change is not entirely peculiar to the hydrophanes. Bergman informs us, that some steatites produce the same effect; and M. Magellan, that the crust of chalcidies and agates frequently produce the same appearance.

Messrs Bruckman and Veltheim were the first who particularly inquired into the nature of this stone, and investigated its properties, many of which were brought to light by their endeavours. Their account is to the following purpose. As soon as the stone is put into water, it exhales a musty smell, several air-bubbles arise, and it becomes gradually transparent. Some of the stones become colourless as soon as they are thoroughly transparent, others have a more or less deep yellow colour; some acquire a beautiful ruby colour; and, lastly, others gain a fine colour of mother-of-pearl, or of a bluish opal. Whatever be the colour of the liquor in which the hydrophanes is immersed, it gains only its usual degree of transparency with the colour peculiar to it. When we look at it in its moist state,

Hydrom-
phales,
Hydro-
phanes.

Hydro-
phobia
||
Hydro-
phyllax.

we perceive a luminous point, varying its situation as the position of the eye is altered. This luminous point is not, according to Mr Bruckman, the immediate image of the sun, but a reflection of that image refracted in the substance of the stone itself, a phenomenon which probably gave rise to the name of *oculus mundi*. Mr Bruckman left a piece of this stone weighing 35 grains seven hours in water, the space requisite to make it perfectly transparent; and in that time he found that it had gained three grains in weight. The hydrophanes becomes much sooner transparent when put into hot water; and the same happens if it be dipped in a very dilute acid, or rather a very dilute solution of alkali. When dipped in oil of vitriol, it becomes very quickly transparent, and will continue so, on account of the strong attraction of that acid for moisture, which takes as much from the atmosphere as is necessary to keep the stone transparent; but its opacity will return if it be dipped in an alkaline liquor and afterwards dried.

HYDROPHOBIA, an aversion or dread of water: a terrible symptom of the *rabies canina*; and which has likewise been found to take in violent inflammations of the stomach and in hysterical fits. See *MEDICINE-Index*.

HYDROPHYLACIA, a word used by Kircher and some others who have written in the same system, to express those great reservoirs of water which he places in the Alps and other mountains for the supply of rivers which run through the several lower countries. This he makes to be one of the great uses of mountains in the economy of the universe.

HYDROPHYLLAX, in botany: A genus of the

monogynia order, belonging to the tetrandia class of plants. The calyx is tetrapartite; the corolla funnel-shaped; the fruit two-edged and one seeded.

HYDROPHYLLUM, WATER-LEAF: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is campanulated, with five melliferous longitudinal stria on the inside; the stigma is bifid; the capsule globose and bivalved. There is only one species, viz. the Virginianum, or water-leaf of Morinus. It grows naturally in Canada and many other parts of America on moist spongy ground. The root is composed of many strong fleshy fibres, from which arise many leaves with foot-stalks five or six inches long, jagged into three, five, or seven lobes, almost to the midrib, indented on their edges. The flowers are produced in loose clusters hanging downward, are bell-shaped, and of a dirty white colour. It may be propagated by parting the roots; which ought to be done in autumn, that the plants may be well rooted before spring, otherwise they will require a great deal of water.

HYDROPS, in medicine, the same with **DROPSY**.

HYDROSCOPE, an instrument anciently used for the measuring of time.

The hydroscope was a kind of water-clock, consisting of a cylindrical tube, conical at bottom: the cylinder was graduated, or marked out with divisions, to which the top of the water becoming successively contiguous, as it trickled out at the vertex of the cone, pointed out the hour. See **HYDROSTATICS**, sect. vi.
